

## 2ED2108 (4) S06F (J)

### 650 V half bridge gate driver with integrated bootstrap diode

#### Features

- Unique Infineon Thin-Film-Silicon On Insulator (SOI)-technology
- Negative VS transient immunity of 100 V
- Floating channel designed for bootstrap operation
- Operating voltages (VS node) upto + 650 V
- Maximum bootstrap voltage (VB node) of + 675 V
- Integrated ultra-fast, low resistance bootstrap diode
- Logic operational up to -11 V on VS Pin
- Negative voltage tolerance on inputs of -5 V
- Independent under voltage lockout for both channels
- Schmitt trigger inputs with hysteresis
- 3.3 V, 5 V and 15 V input logic compatible
- Maximum supply voltage of 25 V
- Dual package options of DSO-8 and DSO-14
- High and low voltage pins separated for maximum creepage and clearance (2ED21084S06J version)
- Separate logic and power ground with the 2ED21084S06J version
- Interlocking function with internal 540 ns dead time and programmable up to 5 us with external resistor (2ED21084S06J only)
- RoHS compliant

#### Product summary

$V_{S\_OFFSET} = 650 \text{ V max.}$   
 $I_{O+pk} / I_{O-pk} (\text{typ.}) = + 0.29 \text{ A} / - 0.7 \text{ A}$   
 $V_{CC} = 10 \text{ V to } 20 \text{ V}$   
 Delay Matching = 35 ns max.  
 Internal deadtime = 540 ns typ.  
 $t_{ON} / t_{OFF} (\text{typ.}) = 200 \text{ ns} / 200 \text{ ns}$

#### Packages

DSO-8

DSO-14

#### Potential applications

Driving IGBTs, enhancement mode N-Channel MOSFETs in various power electronic applications.

Typical Infineon recommendations are as below:

- Motor drives, general purpose inverters having TRENCHSTOP™ IGBT6 or 600 V EasyPACK™ modules or its equivalent power stages
- Refrigeration compressors, induction cookers, other major home appliances having RCD series IGBTs or TRENCHSTOP™ family IGBTs or their equivalent power stages
- Battery operated small home appliances such as power tools, vaccum cleaners using low voltage OptiMOS™ MOSFETs or their equivalent power stages
- Totem pole, half-bridge and full-bridge converters in offline AC-DC power supplies for industrial SMPS having high voltage CoolMOS™ super junction MOSFETs or TRENCHSTOP™ H3 and WR5 IGBT series or their equivalent
- High power LED and HID lighting having CoolMOS™ super junction MOSFETs
- Electric vehicle (EV) charging stations and battery management systems
- Driving 650 V SiC MOSFETs in above applications

#### Product validation

Qualified for industrial applications according to the relevant tests of JEDEC47/20/22

#### Ordering information

### Description

The 2ED2108 (4) S06F (J) is a high voltage, high speed power MOSFET and IGBT driver with independent high and low side referenced output channels. Based on Infineon’s SOI-technology there is an excellent ruggedness and noise immunity with capability to maintain operational logic at negative voltages of up to - 11 V on VS pin ( $V_{CC} = 15 V$ ) on transient voltages. There are not any parasitic thyristor structures present in the device, hence no parasitic latch up may occur at all temperature and voltage conditions. The logic input is compatible with standard CMOS or LSTTL output, down to 3.3 V logic. The output drivers feature a high pulse current buffer stage designed for minimum driver cross-conduction. The floating channel can be used to drive an N-channel power MOSFET, SiC MOSFET or IGBT in the high side configuration, which operate up to 650 V.

Figure 1 Typical application block diagram

### Summary of feature comparison of the 2ED210x family:

Table 1

Part No.	Input logic	Cross conduction prevention logic	Deadtime	Ground pins	$t_{ON} / t_{OFF}$	Package

#### 3.2 Pin functionality

Table 2

Symbol	Description
VCC	Low-side and logic supply voltage
HIN	Logic input for high-side gate driver output (HO), in phase. Schmitt trigger inputs with hysteresis and pull down
/LIN	Logic input for low-side gate driver output (LO), out of phase. Schmitt trigger inputs with hysteresis and pull up
DT	Programmable dead time pin, referenced to Vss (2ED21084S06J only)
VSS	Logic ground ( 2ED21084S06J only)
COM	Low-side gate drive return
LO	Low-side driver output
VS	High voltage floating supply return
HO	High-side driver output
VB	High-side gate drive floating supply

## 4 Electrical parameters

### 4.1 Absolute maximum ratings

Absolute maximum ratings indicate sustained limits beyond which damage to the device may occur. All voltage parameters are absolute voltages referenced to COM unless otherwise stated in the table. The thermal resistance and power dissipation ratings are measured under board mounted and still air conditions.

**Table 3 Absolute maximum ratings**

Symbol	Definition	Min.	Max.	Units	
$V_B$	High-side floating well supply voltage <sup>Note 1</sup>	$V_{CC} - 5$	675	V	
$V_S$	High-side floating well supply return voltage	$V_{CC} - V_{BS} - 5$	650		
$V_{HO}$	Floating gate drive output voltage	$V_S - 0.5$	$V_B + 0.5$		
$V_{BS}$	Floating gate drive voltage supply voltage	-1	25		
$V_{CC}$	Low side supply voltage	-1	25		
$V_{LO}$	Low-side output voltage	-0.5	$V_{CC} + 0.5$		
$V_{IN}$	Logic input voltage	$-5 / (V_{SS} - 5)$	$V_{CC} + 0.5$		
DT	Programmable dead time pin voltage (2ED21084S06J only)	$V_{SS} - 0.5$	$V_{CC} + 0.5$		
$V_{SS}$	Logic ground (2ED21084S06J only)	$V_{CC} - 25$	$V_{CC} + 0.5$		
dV <sub>S</sub> /dt	Allowable $V_S$ offset supply transient relative to COM	—	50		V/ns
$P_D$	Package power dissipation @ $T_A \leq +25^\circ\text{C}$	8 - Lead DSO - 8	—	0.625	W
		14 - Lead DSO - 14	—	1	
Rth <sub>JA</sub>	Thermal resistance, junction to ambient	8 - Lead DSO - 8	—	200	°C/W
		14 - Lead DSO - 14	—	120	
$T_J$	Junction temperature	—	150	°C	
$T_S$	Storage temperature	-55	150		
$T_L$	Lead temperature (soldering, 10 seconds)	—	300		

Note 1: In case  $V_{CC} > V_B$  there is an additional power dissipation in the internal bootstrap diode between pins  $V_{CC}$  and  $V_B$  in case of activated bootstrap diode.

### 4.2 Recommended operating conditions

For proper operation, the device should be used within the recommended conditions. All voltage parameters are absolute voltages referenced to COM unless otherwise stated in the table. The offset rating is tested with supplies of  $(V_{CC} - \text{COM}) = (V_B - V_S) = 15 \text{ V}$ .

**Table 4 Recommended operating conditions**

Symbol	Definition	Min	Max	Units
$V_B$	Bootstrap voltage	$V_S + 10$	$V_S + 20$	V
$V_{BS}$	High-side floating well supply voltage	10	20	
$V_S$	High-side floating well supply offset voltage <sup>Note 2</sup>	$V_{CC} - V_{BS} - 1$	650	
$V_{HO}$	Floating gate drive output voltage	$V_S$	$V_B$	
$V_{CC}$	Low-side supply voltage	10	20	
$V_{LO}$	Low-side output voltage	COM	$V_{CC}$	
$V_{IN}$	Logic input voltage	$-4 / (V_{SS} - 4)$	$5 / (V_{SS} + 5)$	
DT	Programmable dead time pin voltage (2ED21084S06J only)	$V_{SS}$	+5	
$V_{SS}$	Logic ground (2ED21084S06J only) with respect to COM	-5	+5	
$T_A$	Ambient temperature	-40	125	

Note 2: Logic operation for  $V_S$  of -11 V to +650 V.

### 4.3 Static electrical characteristics

$(V_{CC} - COM) = (V_B - V_S) = 15\text{ V}$ ,  $V_{SS} = COM$  and  $T_A = 25\text{ °C}$  unless otherwise specified. The  $V_{IL}$ ,  $V_{IH}$  and  $I_{IN}$  parameters are referenced to  $V_{SS} / COM$  and are applicable to the respective input leads: HIN and /LIN. The  $V_O$  and  $I_O$  parameters are referenced to  $V_S / COM$  and are applicable to the respective output leads HO or LO. The  $V_{CCUV}$  parameters are referenced to  $COM$ . The  $V_{BSUV}$  parameters are referenced to  $V_S$ .

**Table 5 Static electrical characteristics**

Symbol	Definition	Min.	Typ.	Max.	Units	Test Conditions	
$V_{BSUV+}$	$V_{BS}$ supply undervoltage positive going threshold	7.6	8.2	8.9	V		
$V_{BSUV-}$	$V_{BS}$ supply undervoltage negative going threshold	6.7	7.2	8.1

		—	750	—		$V_{IN} = 0\text{ V or } 5\text{ V}$ (2ED21084S06J)	
$V_{OH}$	High level output voltage drop, $V_{CC} - V_{LO}$ , $V_B - V_{HO}$	—	0.05	0.2	V	$I_O = 2\text{ mA}$	
$V_{OL}$	Low level output voltage drop, $V_O$	—	0.02	0.1			
$I_{O+mean}$	Mean output current from 3 V to 6 V	180	230	—	mA	$C_L = 22\text{ nF}$ $V_O = 0\text{ V}$	
$I_{O+}$	Peak output current turn-on <sup>1</sup>	—	290	—			
$I_{O-mean}$	Mean output current from 12 V to 9 V	450	650	—			$C_L = 22\text{ nF}$ $V_O = 15\text{ V}$
$I_{O-}$	Peak output current turn-off <sup>1</sup>	—	700	—			
$V_{IH}$	Logic “1” input voltage	1.7	2.1	2.4	V	$V_{CC} = 10\text{ V to } 20\text{ V}$	
$V_{IL}$	Logic “0” input voltage	0.7	0.9	1.1			
$V_{SD,TH+}$	/SD input positive going threshold	1.7	2.1	2.4			
$V_{SD,TH-}$	/SD input negative going threshold	0.7	0.9	1.1			
$I_{IN+}$	Input bias current (Output = High)	—	25	50	µA	$HIN = 5\text{ V}$ , /LIN = 0 V	
$I_{IN-}$	Input bias current (Output = Low)	—	—	10			$HIN = 0\text{ V}$ , /LIN = 5 V
$V_{FBSD}$	Bootstrap diode forward voltage between $V_{CC}$ and $V_B$	—	1	1.2	V	$I_F = 0.3\text{ mA}$	
$I_{FBSD}$	Bootstrap diode forward current between $V_{CC}$ and $V_B$	45	85	—	mA	$V_{CC} - V_B = 4\text{ V}$	
$R_{BSD}$	Bootstrap diode resistance	20	30	45	Ω	$V_{F1} = 4\text{ V}$ , $V_{F2} = 5\text{ V}$	
$V_S$	Allowable Negative VS pin voltage for IN Signal propagation to HO	—	-11	-10	V	$V_{CC} = 15\text{ V}$	

<sup>1</sup> Not subjected to production test, verified by characterization.

#### 4.4 Dynamic electrical characteristics

$V_{CC} = V_{BS} = 15\text{ V}$ ,  $V_{SS} = \text{COM}$ ,  $T_A = 25\text{ °C}$  and  $C_L = 1000\text{ pF}$  unless otherwise specified.

**Table 6** Dynamic electrical characteristics

Symbol	Definition	Min.	Typ.	Max.	Units	Test Conditions
$t_{ON}$	Turn-on propagation delay	—	200	300	ns	$V_{IN} = 0\text{ V or }5\text{ V}$ $V_S = 0\text{ V}$
$t_{OFF}$	Turn-off propagation delay	—	200	300		
$t_R$	Turn-on rise time	—	100	150		
$t_F$	Turn-off fall time	—	35	80		
MT	Delay matching time (HS & LS turn-on/off)	—	—	35		
DT	Dead time	350	540	730	us	RDT = 0 $\Omega$
		4	5	6		RDT = 200 k $\Omega$
MDT	Matching Dead time	—	0	70	ns	RDT = 0
		—	0	600		RDT = 200 k $\Omega$

## 5 Application information and additional details

### 5.1 IGBT / MOSFET gate drive

The 2ED2108 (4) S06F (J) HVIC is designed to drive MOSFET or IGBT power devices. Figure 4 and Figure 5 illustrate several parameters associated with the gate drive functionality of the HVIC. The output current of the HVIC, used to drive the gate of the power switch, is defined as  $I_o$ . The voltage that drives the gate of the external power switch is defined as  $V_{HO}$  for the high-side power switch and  $V_{LO}$  for the low-side power switch; this parameter is sometimes generically called  $V_{OUT}$  and in this case does not differentiate between the high-side or low-side output voltage.

Figure 4 HVIC Sourcing current

Figure 5 HVIC Sinking current

### 5.2 Switching and timing relationships

The relationships between the input and output signals of the 2ED2108 (4) S06F (J) are illustrated below in Figure 6 and Figure 7. From these figures, we can see the definitions of several timing parameters (i.e.  $t_{ON}$ ,  $t_{OFF}$ ,  $t_R$ , and  $t_F$ ) associated with this device.

Figure 6 Switching timing diagram

Figure 7 Input/output logic diagram

### 5.3 Deadtime

This family of HVICs features integrated deadtime protection circuitry. The deadtime is fixed for 2ED2108S06F; is programmable for 2ED21084S06J, it is greater design flexibility. The deadtime feature inserts a time period (a minimum deadtime) in which both the high- and low-side power switches are held off; this is done to ensure that the power switch being turned off has fully turned off before the second power switch is turned on. This minimum deadtime is automatically inserted whenever the external deadtime is shorter than internal deadtime; external deadtimes larger than internal deadtime are not modified by the gate driver.

The deadtime circuitry of 2ED2108 (4) S06F (J) is matched with respect to the high- and low-side outputs. Figure 8 defines the two deadtime parameters (i.e.,  $DT_{LO-HO}$  and  $DT_{HO-LO}$ ); the deadtime matching parameter (MDT) associated with the 2ED2108 (4) S06F (J) specifies the maximum difference between  $DT_{LO-HO}$  and  $DT_{HO-LO}$ .

**Figure 8** Deadtime matching waveform definition

The 14-pin variant (2ED21084S06J) provides greater design flexibility with a programmable dead-time feature using an external resistor ( $R_{DT}$ ) connected between the DT pin and VSS pin as shown in Figure 9. A decoupling ceramic capacitor ( $CDT > 1$  nF) is recommended which is parallel with  $R_{DT}$ .

**Figure 9** 14-pin half-bridge variants having adjustable dead-time feature settable with a resistor

Figure 10 shows the linear relationship between the resistor ( $R_{DT}$ ) and dead time. Based on the end application, designers can choose to add the external resistor to increase the dead time. In case the DT pin is left open, the gate driver enters protection mode switching off the output stages. Hence this pin has to be connected to VSS pin with a  $0\ \Omega$  to  $200\ \text{k}\Omega$  resistor based on application requirements. A  $0\ \Omega$  (or shorted) provides a minimum deadtime of  $540\ \text{ns}$  and  $200\ \text{k}\Omega$  provides a maximum deadtime of  $5\ \mu\text{s}$ .

Figure 10 Variation of dead time vs. external resistor ( $R_{DT}$ )

## 5.4 Matched propagation delays

The 2ED2108 (4) S06F (J) is designed with propagation delay matching circuitry. With this feature, the IC's response at the output to a signal at the input requires approximately the same time duration (i.e.,  $t_{ON}$ ,  $t_{OFF}$ ) for both the low-side channels and the high-side channels; the maximum difference is specified by the delay matching parameter (MT). The propagation turn-on delay ( $t_{ON}$ ) of the 2ED2108 (4) S06F (J) is matched to the propagation turn-off delay ( $t_{OFF}$ ).

Figure 11 Delay matching waveform definition

## 5.5 Input logic compatibility

The input pins are based on a TTL and CMOS compatible input-threshold logic that is independent of the  $V_{CC}$  supply voltage. Figure 12 illustrates an input signal to the 2ED2108 (4) S06F (J), its input threshold values, and the logic state of the IC as a result of the input signal. The typical high threshold ( $V_{IH}$ ) of 2.1 V and typical low threshold ( $V_{IL}$ ) of 0.9 V. The input pins are conveniently driven with logic level PWM control signals derived from 3.3 V and 5 V digital power-controller devices. Wider hysteresis (typically 0.9 V) offers enhanced noise immunity compared to traditional TTL logic implementations, where the hysteresis is typically less than 0.5 V. 2ED2108 (4) S06F (J) also features tight control of the input pin threshold voltage levels which eases system design considerations and ensures stable operation across temperature. The 2ED2108 (4) S06F (J) has input pins that are capable of sustaining voltages higher than the bias voltage applied on the  $V_{CC}$  pin of the device.

Figure 12 HIN & /LIN input thresholds

## 5.6 Undervoltage lockout

This IC provides undervoltage lockout protection on both the  $V_{CC}$  (logic and low-side circuitry) power supply and the  $V_{BS}$  (high-side circuitry) power supply. Figure 13 is used to illustrate this concept;  $V_{CC}$  (or  $V_{BS}$ ) is plotted over time and as the waveform crosses the UVLO threshold ( $V_{CCUV+/-}$  or  $V_{BSUV+/-}$ ) the undervoltage protection is enabled or disabled.

Upon power-up, should the  $V_{CC}$  voltage fail to reach the  $V_{CCUV+}$  threshold, the IC won't turn-on. Additionally, if the  $V_{CC}$  voltage decreases below the  $V_{CCUV-}$  threshold during operation, the undervoltage lockout circuitry will recognize a fault condition and shutdown the high and low-side gate drive outputs.

Upon power-up, should the  $V_{BS}$  voltage fail to reach the  $V_{BSUV+}$  threshold, the IC won't turn-on. Additionally, if the  $V_{BS}$  voltage decreases below the  $V_{BSUV-}$  threshold during operation, the undervoltage lockout circuitry will recognize a fault condition, and shutdown the high-side gate drive outputs of the IC.

The UVLO protection ensures that the IC drives the external power devices only when the gate supply voltage is sufficient to fully enhance the power devices. Without this feature, the gates of the external power switch could be driven with a low voltage, resulting in the power switch conducting current while the channel impedance is high; this could result in high conduction losses within the power device and could lead to power device failure.

Figure 13 UVLO protection

## 5.7 Bootstrap diode

An ultra-fast bootstrap diode is monolithically integrated for establishing the high side supply. The differential resistor of the diode helps to avoid extremely high inrush currents when initially charging the bootstrap capacitor. The integrated diode with its resistance helps save cost and improve reliability by reducing external components as shown below Figure 14 and Figure 15.

Figure 14 2ED210x with integrated components

Figure 15 Standard bootstrap gate driver

The low ohmic current limiting resistor provides essential advantages over other competitor devices with high ohmic bootstrap structures. A low ohmic resistor such as in the 2ED210x family allows faster recharging of the bootstrap capacitor during periods of small duty cycles on the low side transistor. The bootstrap diode is a real pn-diode which works with all control algorithms of modern power electronics, such as trapezoidal or sinusoidal motor drives control.

## 5.8 Calculating the bootstrap capacitance $C_{BS}$

Bootstrapping is a common method of pumping charges from a low potential to a higher one. With this technique a supply voltage for the floating high side sections of the gate drive can be easily established according to Figure 16. This method has the advantage of being simple and low cost but may force some limitations on duty-cycle and on-time since they are limited by the requirement to refresh the charge in the bootstrap capacitor. Proper capacitor choice can reduce drastically these limitations.

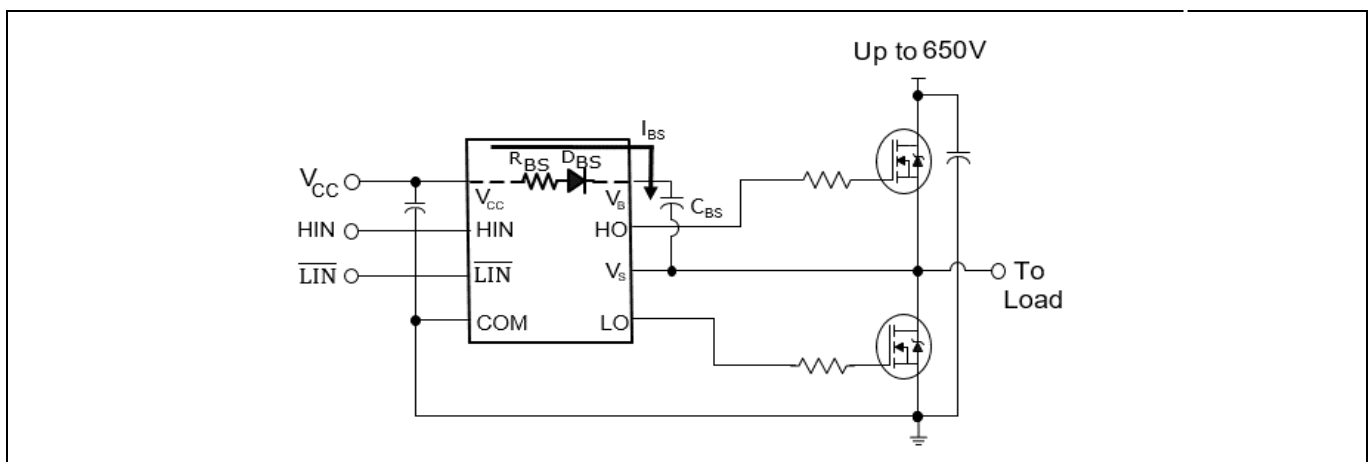

Figure 16 Half bridge bootstrap circuit in 2ED210x

When the low side MOSFET turns on, it will force the potential of pin  $V_S$  to GND. The existing difference between the voltage of the bootstrap capacitor  $V_{CBS}$  and  $V_{CC}$  results in a charging current  $I_{BS}$  into the capacitor  $C_{BS}$ . The

current  $I_{BS}$  is a pulse current and therefore the ESR of the capacitor  $C_{BS}$  must be very small in order to avoid losses in the capacitor that result in lower lifetime of the capacitor. This pin is on high potential again after low side is turned off and high side is conducting current. But now the bootstrap diode  $D_{BS}$  blocks a reverse current, so that the charges on the capacitor cannot flow back to the capacitor  $C_{VCC}$ . The bootstrap diode  $D_{BS}$  also takes over the blocking voltage between pin  $V_B$  and  $V_{CC}$ . The voltage of the bootstrap capacitor can now supply the high side gate drive sections. It is a general design rule for the location of bootstrap capacitors  $C_{BS}$ , that they must be placed as close as possible to the IC. Otherwise, parasitic resistors and inductances may lead to voltage spikes, which may trigger the undervoltage lockout threshold of the individual high side driver section. However, all parts of the 2ED210x family, which have the UVLO also contain a filter at each supply section in order to actively avoid such undesired UVLO triggers.

The current limiting resistor  $R_{BS}$  according to Figure 16 reduces the peak of the pulse current during the low side MOSFET turn-on. The pulse current will occur at each turn-on of the low side MOSFET, so that with increasing switching frequency the capacitor  $C_{BS}$  is charged more frequently. Therefore a smaller capacitor is suitable at higher switching frequencies. The bootstrap capacitor is mainly discharged by two effects: The high side quiescent current and the gate charge of the high side MOSFET to be turned on.

The minimum size of the bootstrap capacitor is given by

$$C_{BS} = \frac{Q_{GTOT}}{\Delta V_{BS}}$$

$\Delta V_{BS}$  is the maximum allowable voltage drop at the bootstrap capacitor within a switching period, typically 1 V. It is recommended to keep the voltage drop below the undervoltage lockout (UVLO) of the high side and limit

$$\Delta V_{BS} \leq (V_{CC} - V_F - V_{GSmin} - V_{DSon})$$

$V_{GSmin} > V_{BSUV-}$ ,  $V_{GSmin}$  is the minimum gate source voltage we want to maintain and  $V_{BSUV-}$  is the high-side supply undervoltage negative threshold.

$V_{CC}$  is the IC voltage supply,  $V_F$  is bootstrap diode forward voltage and  $V_{DSon}$  is drain-source voltage of low side MOSFET.

Please note, that the value  $Q_{GTOT}$  may vary to a maximum value based on different factors as explained below and the capacitor shows voltage dependent derating behavior of its capacitance.

The influencing factors contributing  $V_{BS}$  to decrease are:

- MOSFET turn on required Gate charge ( $Q_G$ )
- MOSFET gate-source leakage current ( $I_{LK\_GS}$ )
- Floating section quiescent current ( $I_{QBS}$ )
- Floating section leakage current ( $I_{LK}$ )
- Bootstrap diode leakage current ( $I_{LK\_DIODE}$ )
- Charge required by the internal level shifters ( $Q_{LS}$ ): typical 1nC
- Bootstrap capacitor leakage current ( $I_{LK\_CAP}$ )
- High side on time ( $T_{HON}$ )

Considering the above,

$$Q_{GTOT} = Q_G + Q_{LS} + (I_{QBS} + I_{LK\_GS} + I_{LK} + I_{LK\_DIODE} + I_{LK\_CAP}) * T_{HON}$$

$I_{LK\_CAP}$  is only relevant when using an electrolytic capacitor and can be ignored if other types of capacitors are used. It is strongly recommend using at least one low ESR ceramic capacitor (paralleling electrolytic capacitor and low ESR ceramic capacitor may result in an efficient solution).

The above  $C_{BS}$  equation is valid for pulse by pulse considerations. It is easy to see, that higher capacitance values are needed, when operating continuously at small duty cycles of low side. The recommended bootstrap capacitance is therefore in the range up to 4.7  $\mu\text{F}$  for most switching frequencies. The performance of the integrated bootstrap diode supports the requirement for small bootstrap capacitances.

## 5.9 Tolerant to negative transients on input pins

Typically the driver's ground pin is connected close to the source pin of the MOSFET or IGBT. The microcontroller which sends the HIN and /LIN PWM signals refers to the same ground and in most cases there will be an offset voltage between the microcontroller ground pin and driver ground because of ground bounce. The 2ED210x family can handle negative voltage spikes up to 5 V. The recommended operating level is at negative 4 V with absolute maximum of negative 5 V. Standard half bridge or high-side/low-side gate drivers only allow negative voltage levels down to -0.3 V. The 2ED210x family has much better noise immunity capability on the input pins.

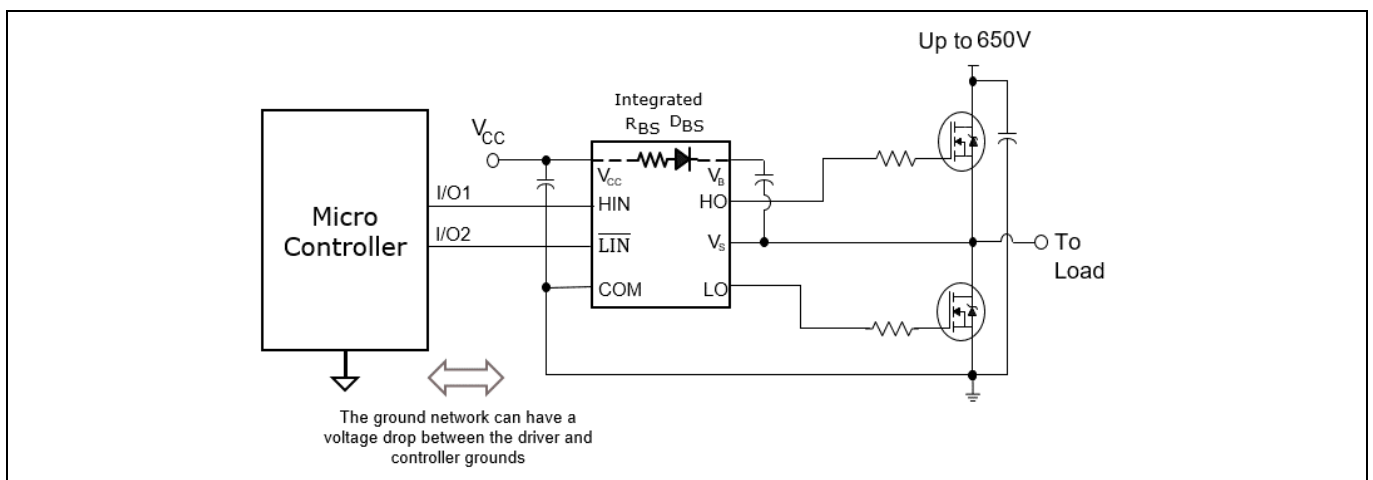

Figure 17 Negative voltage tolerance on inputs of upto -5 V

## 5.10 Negative voltage transient tolerance of VS pin

A common problem in today's high-power switching converters is the transient response of the switch node's voltage as the power switches transition on and off quickly while carrying a large current. A typical 3-phase inverter circuit is shown in Figure 18, here we define the power switches and diodes of the inverter.

If the high-side switch (e.g., the IGBT Q1 in Figure 19) switches from on to off, while the U phase current is flowing to an inductive load, a current commutation occurs from high-side switch (Q1) to the diode (D2) in parallel with the low-side switch of the same inverter leg. At the same instance, the voltage node  $V_{s1}$ , swings from the positive DC bus voltage to the negative DC bus voltage.

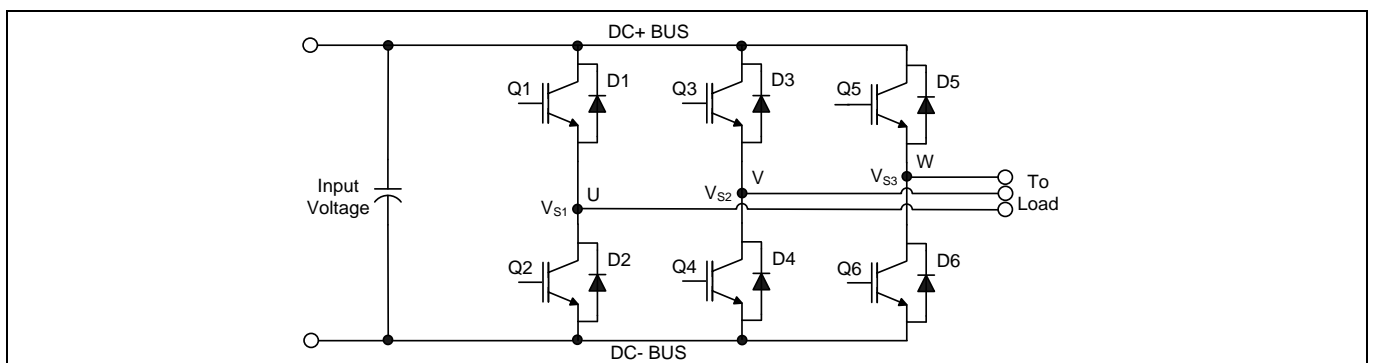

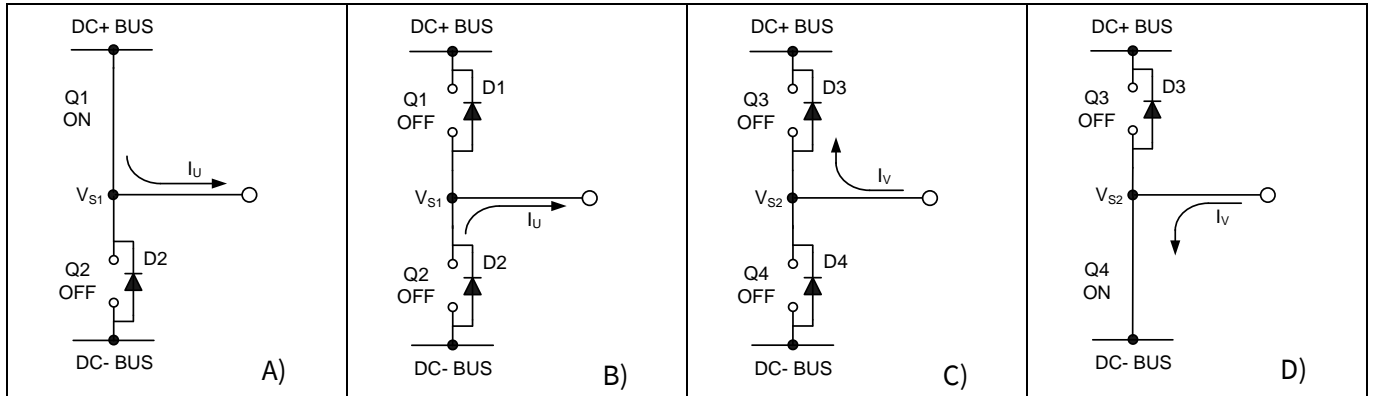

Figure 18 Three phase inverter

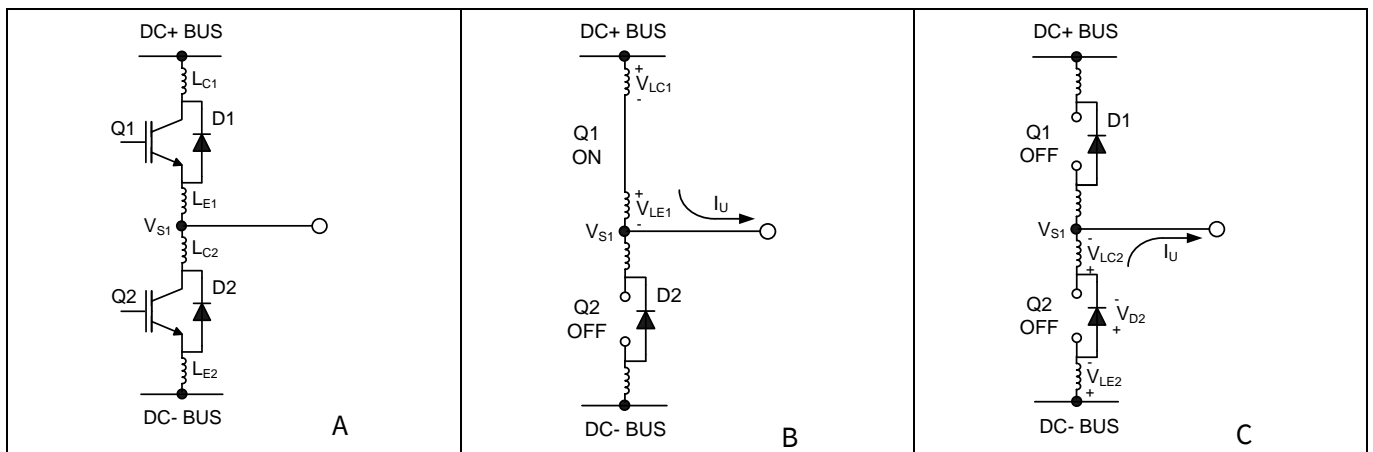

Also when the V phase current flows from the inductive load back to the inverter (see Figure 19 C) and D)), and Q4 IGBT switches on, the current commutation occurs from D3 to Q4. At the same instance, the voltage node,  $V_{S2}$ , swings from the positive DC bus voltage to the negative DC bus voltage.

However, in a real inverter circuit, the  $V_S$  voltage swing does not stop at the level of the negative DC bus, rather it swings below the level of the negative DC bus. This undershoot voltage is called “negative  $V_S$  transient”

**Figure 19 A) Q1 conducting B) D2 conducting C) D3 conducting D) Q4 conducting**

The circuit shown in Figure 20-A depicts one leg of the three phase inverter; Figure 20-B and 19-C show a simplified illustration of the commutation of the current between Q1 and D2. The parasitic inductances in the power circuit from the die bonding to the PCB tracks are lumped together in  $L_C$  and  $L_E$  for each IGBT. When the high-side switch is on,  $V_{S1}$  is below the DC+ voltage by the voltage drops associated with the power switch and the parasitic elements of the circuit. When the high-side power switch turns off, the load current momentarily flows in the low-side freewheeling diode due to the inductive load connected to  $V_{S1}$  (the load is not shown in these figures). This current flows from the DC- BUS (which is connected to the COM pin of the HVIC) to the load and a negative voltage between  $V_{S1}$  and the DC- BUS is induced (i.e., the COM pin of the HVIC is at a higher potential than the  $V_S$  pin).

**Figure 20 Figure A shows the parasitic elements. Figure B shows the generation of  $V_S$  positive. Figure C shows the generation of  $V_S$  negative**

### 5.11 NTSOA – Negative Transient Safe Operating Area

In a typical motor drive system,  $dV/dt$  is typically designed to be in the range of 3 – 5 V / ns. The negative  $V_S$  transient voltage can exceed this range during some events such as short circuit and over-current shutdown, when  $di/dt$  is greater than in normal operation.

Infineon's HVICs have been designed for the robustness required in many of today's demanding applications. An indication of the 2ED2108 (4) S06F (J)'s robustness can be seen in Figure 21, where the 2ED2108 (4) S06F (J)'s Safe Operating Area is shown at  $V_{BS}=15\text{ V}$  based on repetitive negative  $V_S$  spikes. A negative  $V_S$  transient voltage falling in the grey area (outside SOA) may lead to IC permanent damage; viceversa unwanted functional anomalies or permanent damage to the IC do not appear if negative  $V_S$  transients fall inside the SOA.

**Figure 21 Negative  $V_S$  transient SOA for 2ED2108 (4) S06F (J) @  $V_{BS}=15\text{ V}$**

Even though the 2ED2108 (4) S06F(J) has been shown able to handle these large negative  $V_S$  transient conditions, it is highly recommended that the circuit designer always limit the negative  $V_S$  transients as much as possible by careful PCB layout and component use.

## 5.12 Higher headroom for input to output signal transmission with logic operation upto -11 V

If there is not enough voltage for the level shifter to transmit a valid signal to the high side. High side driver doesn't turn on. The level shifter circuit is with respect to COM (refer to Block Diagram on page 4), the voltage from  $V_B$  to COM is the supply voltage of level shifter. Under the condition of  $V_S$  is negative voltage with respect to COM, the voltage of  $V_S - \text{COM}$  is decreased, as shown in Figure 22. There is a minimum operational supply voltage of level shifter, if the supply voltage of level shifter is too low, the level shifter cannot pass through IN signal to HO. The specification of  $V_S$  is -11 V as the internal structure allows a voltage difference of 15 V between  $V_{CC}$  and COM pins. If  $V_B - V_S$  voltage is different, the minimum  $V_S$  voltage changes accordingly.

**Figure 22 Headroom for HV level shifter data transmission**

### 5.13 Maximum switching frequency

The 2ED210x family is capable of switching at higher frequencies as compared to standard half-bridge or high side / low side gate drivers. They are available in two packages, the PG-DSO-8 and the PG-DSO-14. It is essential to ensure that the component is not thermally overloaded when operating at higher frequencies. This can be checked by means of the thermal resistance junction to ambient and the calculation or measurement of the dissipated power. The thermal resistance is given in the datasheet (section 4) and refers to a specific layout. Changes of this layout may lead to an increased thermal resistance, which will reduce the total dissipated power of the driver IC. One should therefore do temperature measurements in order to avoid thermal overload under application relevant conditions of ambient temperature and housing.

The maximum chip temperature  $T_J$  can be calculated with

$$T_J = P_d \cdot R_{th_{JA}} + T_{A_{max}}, \text{ where } T_{A_{max}} \text{ is the maximum ambient temperature.}$$

The dissipated power  $P_d$  by the driver IC is a combination of several sources. These are explained in detail in the application note “2ED2108 (4) S06F (J) (HVICs)”

Here is the example of the figures which estimates the gate driver IC junction temperature when switching a given MOSFET at different switching frequencies.

\*Assumptions for above curves: LLC topology, Power switch = IPP60R600P6,  $T_a = 25\text{ }^\circ\text{C}$ ,  $V_{BUS} = 400\text{ V}$ ,  $V_{CC} = 12\text{ V}$ ,  $R_{gon} = 3.9\ \Omega$ ,  $R_{goff} = 1\ \Omega$

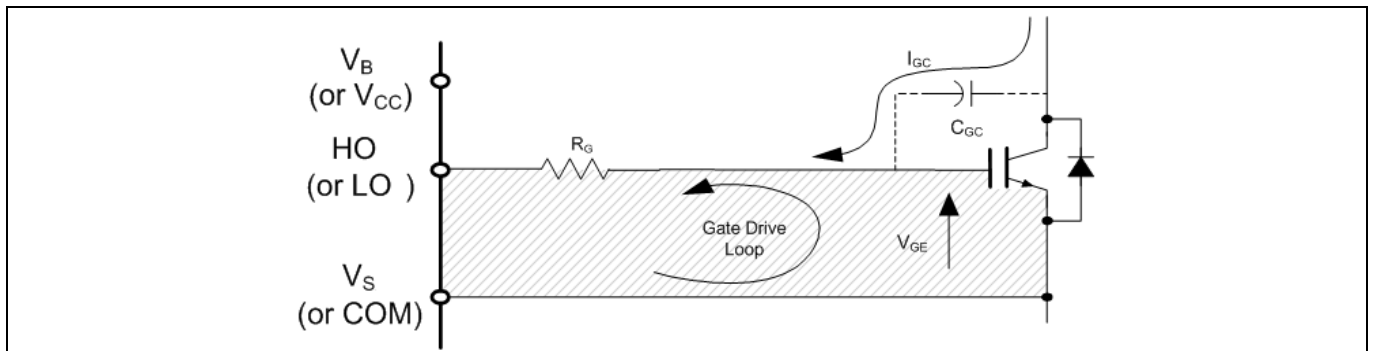

**Figure 23** Estimated  $T_J$  vs. Frequencies (Left: DSO-8, Right: DSO-14)

## 5.14 PCB layout tips

**Distance between high and low voltage components:** It's strongly recommended to place the components tied to the floating voltage pins ( $V_B$  and  $V_S$ ) near the respective high voltage portions of the device. Please see the Case Outline information in this datasheet for the details.

**Ground Plane:** In order to minimize noise coupling, the ground plane should not be placed under or near the high voltage floating side.

**Gate Drive Loops:** Current loops behave like antennas and are able to receive and transmit EM noise (see Figure 24). In order to reduce the EM coupling and improve the power switch turn on/off performance, the gate drive loops must be reduced as much as possible. Moreover, current can be injected inside the gate drive loop via the IGBT collector-to-gate parasitic capacitance. The parasitic auto-inductance of the gate loop contributes to developing a voltage across the gate-emitter, thus increasing the possibility of a self turn-on effect.

**Figure 24 Avoid antenna loops**

**Supply Capacitor:** It is recommended to place a bypass capacitor ( $C_{IN}$ ) between the  $V_{CC}$  and COM pins. A ceramic  $1\mu\text{F}$  ceramic capacitor is suitable for most applications. This component should be placed as close as possible to the pins in order to reduce parasitic elements.

**Routing and Placement:** Power stage PCB parasitic elements can contribute to large negative voltage transients at the switch node; it is recommended to limit the phase voltage negative transients. In order to avoid such conditions, it is recommended to 1) minimize the high-side emitter to low-side collector distance, and 2) minimize the low-side emitter to negative bus rail stray inductance. However, where negative  $V_S$  spikes remain excessive, further steps may be taken to reduce the spike. This includes placing a resistor ( $5\ \Omega$  or less) between the  $V_S$  pin and the switch node (see Figure 25 - A), and in some cases using a clamping diode between COM and  $V_S$  (see Figure 25 - B). See DT04-4 at [www.infineon.com](http://www.infineon.com) for more detailed explanations.

**Figure 25 Resistor between the  $V_S$  pin and the switch node and clamping diode between COM and  $V_S$**

## 6 Qualification information<sup>1</sup>

**Table 7 Qualification information**

Qualification level		Industrial <sup>2</sup>	
		Note: This family of ICs has passed JEDEC's Industrial qualification. Consumer qualification level is granted by extension of the higher Industrial level.	
Moisture sensitivity level		DSO-8	MSL2, 260°C (per IPC/JEDEC J-STD-020)
		DSO-14	MSL3 <sup>3</sup> , 260°C (per IPC/JEDEC J-STD-020)
ESD	Charged device model	Class C3 (1.0 kV) (per JEDEC standard JS-002)	
	Human body model	Class 1C (1.5 kV) (per JEDEC standard JS-001)	
IC latch-up test		Class II Level A (per JESD78)	
RoHS compliant		Yes

### 10.1 Infineon online forum resources

The Gate Driver Forum is live at Infineon Forums ([www.infineonforums.com](http://www.infineonforums.com)). This online forum is where the Infineon gate driver IC community comes to the assistance of our customers to provide technical guidance – how to use gate drivers ICs, existing and new gate driver information, application information, availability of demo boards, online training materials for over 500 gate driver ICs. The Gate Driver Forum also serves as a repository of FAQs where the user can review solutions to common or specific issues faced in similar applications.

Register online at the Gate Driver Forum and learn the nuances of efficiently driving a power switch in any given power electronic application.

## 11 Revision history

Document version	Date of release	Description of changes
2.00	Aug. 08, 2019	Final Datasheet
2.10	Sep. 12, 2019	Revised parameter values in Table 7 to match the test conditions.
2.20	Jan. 14, 2020	Revised parameter values in Table 7 to match the test conditions. Added deadtime settings section in page 10-11. Updated the laser marking for DSO14
2.21	April 07, 2020	Changed the ESD HBM from Class 2 to Class 1C
2.22	July 02, 2020	IC latch-up test per JESD78
2.30	June 1, 2021	Added recommended CDT capacitor on deadtime pin as shown in figure 9. Updated block diagrams in figure 2.
2.31	Oct. 11, 2021	Merge V2.22 and V2.30. Added interlocking function under Features section on page 1.
2.32	May 12, 2022	Remove $I_{FBS}$ maximum spec
