

FEATURES

- 8 software-programmable output ranges: 0 V to 5 V, 0 V to 10 V, 0 V to 16 V, 0 V to 20 V, ± 3 V, ± 5 V, ± 10 V, -2.5 V to $+7.5$ V; 5% overrange**
- Total unadjusted error (TUE): 0.1% FSR maximum**
- 16-bit accuracy: ± 2 LSB maximum**
- Guaranteed monotonicity: ± 1 LSB maximum**
- Single channel, 16-/12-bit DACs**
- Settling time: 7.5 μ s typical**
- Integrated reference buffers**
- Low noise: 35 nV/ $\sqrt{\text{Hz}}$**
- Low glitch: 1 nV-sec**
- 1.8 V logic compatibility**
- Asynchronous updating via $\overline{\text{LDAC}}$**
- Asynchronous $\overline{\text{RESET}}$ to zero scale/midscale**
- DSP/microcontroller-compatible serial interface**
- Robust 4 kV HBM ESD rating**
- Operating temperature range: -40°C to $+125^\circ\text{C}$**

APPLICATIONS

- Industrial automation
- Instrumentation, data acquisition
- Open-/closed-loop servo control, process control
- Programmable logic controllers

GENERAL DESCRIPTION

The AD5761/AD5721 are single channel, 16-/12-bit serial input, voltage output, digital-to-analog converters (DACs). They operate from single supply voltages from 4.75 V to 30 V or dual supply voltages from -16.5 V to 0 V V_{SS} and 4.75 V to 16.5 V V_{DD} . The integrated output amplifier and reference buffer provide a very easy to use, universal solution.

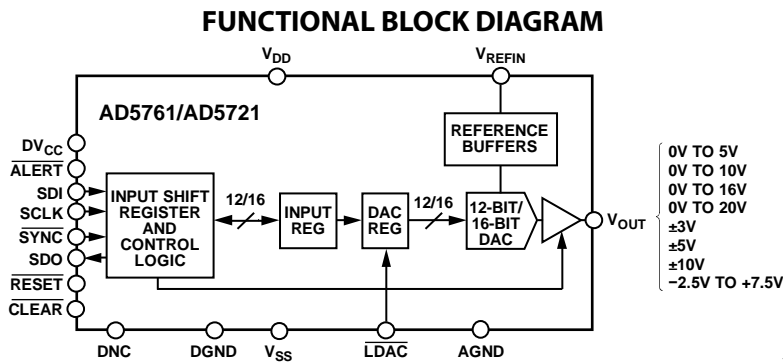

The devices offer guaranteed monotonicity, integral nonlinearity (INL) of ± 2 LSB maximum, 35 nV/ $\sqrt{\text{Hz}}$ noise, and 7.5 μ s settling time on selected ranges.

The AD5761/AD5721 use a serial interface that operates at clock rates of up to 50 MHz and are compatible with DSP and microcontroller interface standards. Double buffering allows the asynchronous updating of the DAC output. The input coding is user-selectable twos complement or straight binary. The asynchronous reset function resets all registers to their default state. The output range is user selectable, via the RA[2:0] bits in the control register.

The devices available in the 16-lead TSSOP package offer guaranteed specifications over the -40°C to $+125^\circ\text{C}$ industrial temperature range.

LOGIC OUTPUTS (SDO, ALERT) ⁵					
Output Voltage					
Low, V_{OL}			0.4	V	$DV_{CC} = 1.7\text{ V}$ to 5.5 V, sinking 200 μA
High, V_{OH}	$DV_{CC} - 0.5$			V	$DV_{CC} = 1.7\text{ V}$ to 5.5 V, sourcing 200 μA
High Impedance, SDO Pin					
Leakage Current	-1		+1	μA	
Pin Capacitance		5		pF	
POWER REQUIREMENTS					
V_{DD}	4.75		30	V	
V_{SS}	-16.5		0	V	
DV_{CC}	1.7		5.5	V	
I_{DD}		5.1	6.5	mA	Outputs unloaded, external reference
I_{SS}		1	3	mA	Outputs unloaded
$D I_{CC}$		0.005	1	μA	$V_{IH} = DV_{CC}$, $V_{IL} = \text{DGND}$
Power Dissipation		67.1		mW	$\pm 11\text{ V}$ operation, outputs unloaded
DC Power Supply Rejection Ratio (PSRR) ⁵		0.1		mV/V	$V_{DD} \pm 10\%$, $V_{SS} = -15\text{ V}$
		0.1		mV/V	$V_{SS} \pm 10\%$, $V_{DD} = +15\text{ V}$
AC PSRR ⁵		80		dB	$V_{DD} \pm 200\text{ mV}$, 50 Hz/60 Hz, $V_{SS} = -15\text{ V}$; external reference; $C_{LOAD} = \text{unloaded}$
		80		dB	$V_{SS} \pm 200\text{ mV}$, 50 Hz/60 Hz, $V_{DD} = +15\text{ V}$; external reference; $C_{LOAD} = \text{unloaded}$

¹ For specified performance, headroom requirement is 1 V.

² Temperature range: -40°C to $+125^{\circ}\text{C}$, typical at $+25^{\circ}\text{C}$.

³ External reference means 2 V to 2.85 V with overrange and 2 V to 3 V without overrange.

⁴ Integral nonlinearity error is specified at $\pm 4\text{ LSB}$ (minimum/maximum) for 0 V to 16 V and 0 V to 20 V ranges with $V_{REFIN} = 2.5\text{ V}$ external reference, and for all ranges with $V_{REFIN} = 2\text{ V}$ to 2.85 V with overrange and 2 V to 3 V without overrange.

⁵ Guaranteed by design and characterization, not production tested.

AC PERFORMANCE CHARACTERISTICS

$V_{DD}^1 = 4.75 \text{ V to } 30 \text{ V}$, $V_{SS}^1 = -16.5 \text{ V to } 0 \text{ V}$, $AGND = DGND = 0 \text{ V}$, $V_{REFIN} = 2.5 \text{ V external}$, $DV_{CC} = 1.7 \text{ V to } 5.5 \text{ V}$, $R_{LOAD} = 1 \text{ k}\Omega$ for all ranges except $0 \text{ V to } 16 \text{ V}$ and $0 \text{ V to } 20 \text{ V}$ for which $R_{LOAD} = 2 \text{ k}\Omega$, $C_{LOAD} = 200 \text{ pF}$, all specifications T_{MIN} to T_{MAX} , unless otherwise noted.

Table 3.

Parameter ²	Min	Typ	Max	Unit	Test Conditions/Comments
DYNAMIC PERFORMANCE³					
Output Voltage Settling Time		9	12.5	μs	20 V step to 1 LSB at 16-bit resolution
		7.5	8.5	μs	10 V step to 1 LSB at 16-bit resolution
			5	μs	512 LSB step to 1 LSB at 16-bit resolution
Digital-to-Analog Glitch Impulse		8		nV-sec	$\pm 10 \text{ V range}$
Glitch Impulse Peak Amplitude		1		nV-sec	0 V to 5 V range
		15		mV	$\pm 10 \text{ V range}$
Power-On Glitch		10		mV	0 V to 5 V range
		100		mV p-p	
Digital Feedthrough		0.6		nV-sec	
Output Noise					
0.1 Hz to 10 Hz Bandwidth (BW)		15		$\mu\text{V p-p}$	
100 kHz BW		45		$\mu\text{V rms}$	0 V to 20 V and 0 V to 16 V ranges, 2.5 V external reference
		35		$\mu\text{V rms}$	0 V to 10 V, $\pm 10 \text{ V}$, $-2.5 \text{ V to } +7.5 \text{ V}$ ranges, 2.5 V external reference
		25		$\mu\text{V rms}$	$\pm 5 \text{ V range}$, 2.5 V external reference
		15		$\mu\text{V rms}$	$+5 \text{ V}$, $\pm 3 \text{ V}$ ranges; 2.5 V external reference
Output Noise Spectral Density (at 10 kHz)		80		nV/ $\sqrt{\text{Hz}}$	$\pm 10 \text{ V range}$, 2.5 V external reference
		35		nV/ $\sqrt{\text{Hz}}$	$\pm 3 \text{ V range}$, 2.5 V external reference
		70		nV/ $\sqrt{\text{Hz}}$	$\pm 5 \text{ V}$, 0 V to 10 V, and $-2.5 \text{ V to } +7.5 \text{ V}$ ranges; 2.5 V external reference
		110		nV/ $\sqrt{\text{Hz}}$	0 V to 20 V range, 2.5 V external reference
		90		nV/ $\sqrt{\text{Hz}}$	0 V to 16 V range, 2.5 V external reference
	45		nV/ $\sqrt{\text{Hz}}$	0 V to 5 V range, 2.5 V external reference	
Total Harmonic Distortion (THD) ⁴		-87		dB	2.5 V external reference, 1 kHz tone
Signal-to-Noise Ratio (SNR)		92		dB	At ambient, 2.5 V external reference, BW = 20 kHz, $f_{OUT} = 1 \text{ kHz}$
Peak Harmonic or Spurious Noise (SFDR)		92		dB	At ambient, 2.5 V external reference, BW = 20 kHz, $f_{OUT} = 1 \text{ kHz}$
Signal-to-Noise-and-Distortion (SINAD) Ratio		85		dB	At ambient, 2.5 V external reference, BW = 20 kHz, $f_{OUT} = 1 \text{ kHz}$

¹ For specified performance, headroom requirement is 1 V.

² Temperature range: -40°C to $+125^\circ\text{C}$, typical at $+25^\circ\text{C}$.

³ Guaranteed by design and characterization; not production tested.

⁴ Digitally generated sine wave at 1 kHz.

TIMING CHARACTERISTICS

$DV_{CC} = 1.7\text{ V to }5.5\text{ V}$, all specifications T_{MIN} to T_{MAX} , unless otherwise noted.

Table 4.

Parameter	Limit at T_{MIN} to T_{MAX}	Unit	Description
t_1^1	20	ns min	SCLK cycle time
t_2	10	ns min	SCLK high time
t_3	10	ns min	SCLK low time
t_4	15	ns min	$\overline{\text{SYNC}}$ falling edge to SCLK falling edge setup time
t_5	10	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ rising edge time
t_6	20	ns min	Minimum $\overline{\text{SYNC}}$ high time (write mode)
t_7	5	ns min	Data setup time
t_8	5	ns min	Data hold time
t_9	10	ns min	$\overline{\text{LDAC}}$ falling edge to $\overline{\text{SYNC}}$ falling edge
t_{10}	20	ns min	$\overline{\text{SYNC}}$ rising edge to $\overline{\text{LDAC}}$ falling edge
t_{11}	20	ns min	$\overline{\text{LDAC}}$ pulse width low
t_{12}	9	$\mu\text{s typ}$	DAC output settling time, 20 V step to 1 LSB at 16-bit resolution (see Table 3)
	7.5	$\mu\text{s typ}$	DAC output settling time, 10 V step to 1 LSB at 16-bit resolution
t_{13}	20	ns min	$\overline{\text{CLEAR}}$ pulse width low
t_{14}	200	ns typ	$\overline{\text{CLEAR}}$ pulse activation time
t_{15}	10	ns min	$\overline{\text{SYNC}}$ rising edge to SCLK falling edge
t_{16}	40	ns max	SCLK rising edge to SDO valid ($C_{L_SDO} = 15\text{ pF}$, where C_{L_SDO} is the capacitive load on the SDO output)
t_{17}	50	ns min	Minimum $\overline{\text{SYNC}}$ high time (readback/daisy-chain mode)

¹ Maximum SCLK frequency is 50 MHz for write mode and 33 MHz for readback mode.

Timing Diagrams

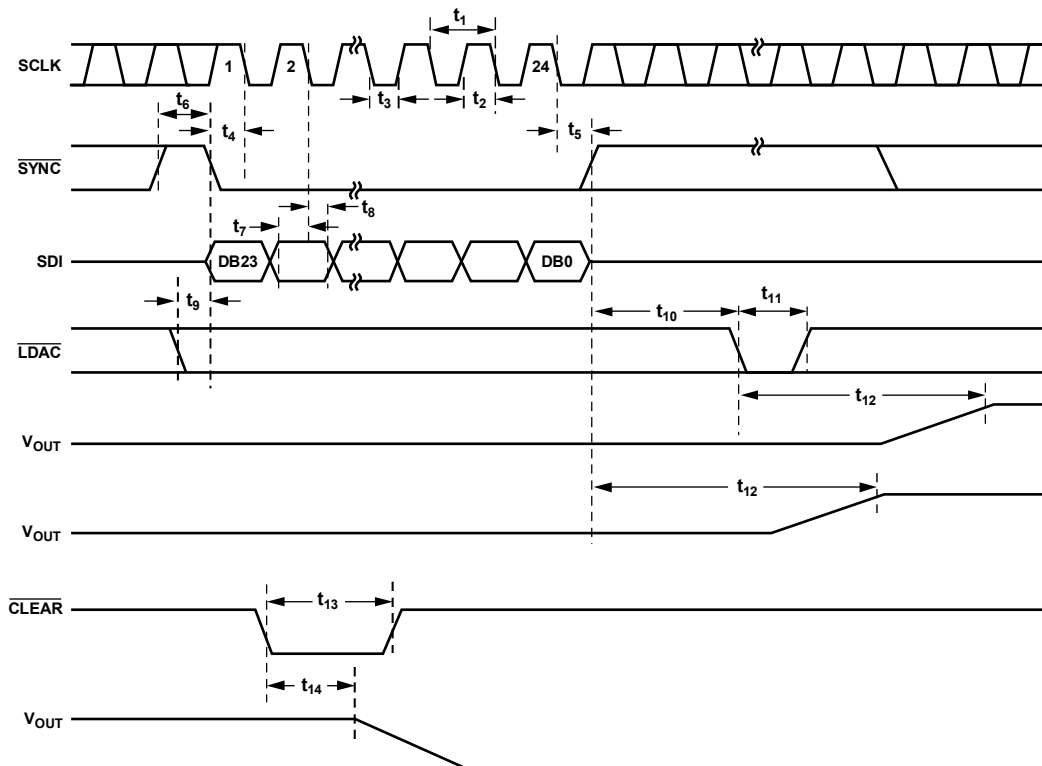

Figure 2. Serial Interface Timing Diagram

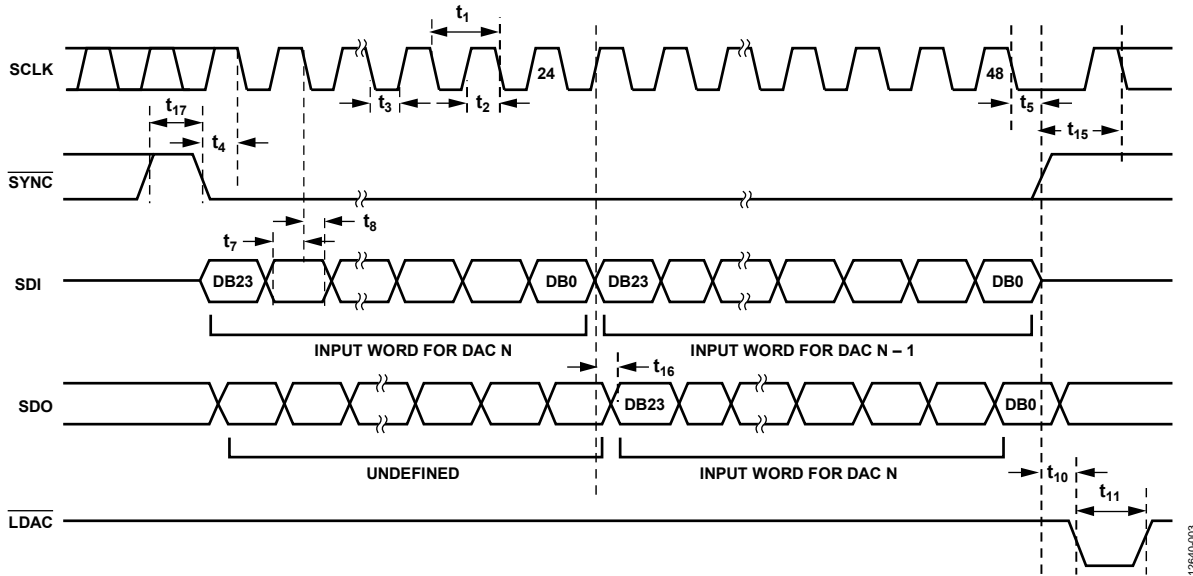

Figure 3. Daisy-Chain Timing Diagram

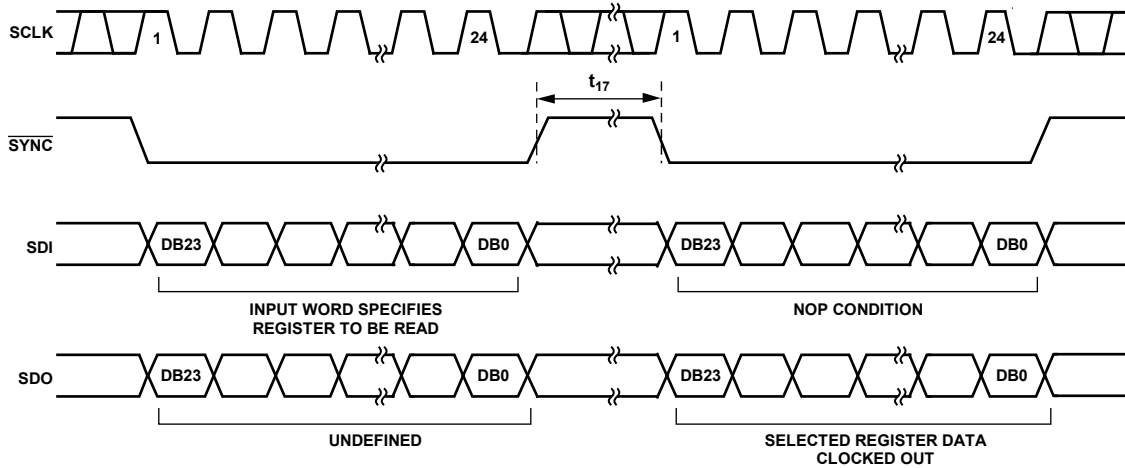

Figure 4. Readback Timing Diagram

ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$, unless otherwise noted. Transient currents of up to 200 mA do not cause silicon controlled rectifier (SCR) latch-up.

Table 5.

Parameter	Rating
V_{DD} to AGND	-0.3 V to +34 V
V_{SS} to AGND	+0.3 V to -17 V
V_{DD} to V_{SS}	-0.3 V to +34 V
DV_{CC} to DGND	-0.3 V to +7 V
Digital Inputs ¹ to DGND	-0.3 V to $DV_{CC} + 0.3$ V or 7 V (whichever is less)
Digital Outputs ² to DGND	-0.3 V to $DV_{CC} + 0.3$ V or 7 V (whichever is less)
V_{REFIN} to DGND	-0.3 V to +7 V
V_{OUT} to AGND	V_{SS} to V_{DD}
AGND to DGND	-0.3 V to +0.3 V
Operating Temperature Range, T_A Industrial	-40°C to +125°C
Storage Temperature Range	-65°C to +150°C
Junction Temperature, $T_{J\text{MAX}}$	150°C
16-Lead TSSOP Package	
θ_{JA} Thermal Impedance ³	113°C/W
θ_{JC} Thermal Impedance	28°C/W
Power Dissipation	$(T_{J\text{MAX}} - T_A)/\theta_{JA}$
Lead Temperature	JEDEC industry standard
Soldering	J-STD-020
ESD (Human Body Model)	4 kV

¹ The digital inputs include $\overline{\text{CLEAR}}$, $\overline{\text{RESET}}$, $\overline{\text{SCLK}}$, $\overline{\text{SYNC}}$, $\overline{\text{SDI}}$, and $\overline{\text{LDAC}}$.

² The digital outputs include $\overline{\text{ALERT}}$ and $\overline{\text{SDO}}$.

³ JEDEC 2S2P test board, still air (0 m/sec airflow).

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

DNC = DO NOT CONNECT. DO NOT CONNECT TO THIS PIN.

Figure 5. Pin Configuration

12840-006

Table 6. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	ALERT	Active Low Alert. This pin is asserted low when the die temperature exceeds approximately 150°C, or when an output short circuit or a brownout occurs. This pin is also asserted low during power-up, a full software reset, or a hardware reset, for which a write to the control register asserts the pin high.
2	CLEAR	Falling Edge Clear Input. Asserting this pin sets the DAC register to zero-scale, midscale, or full-scale code (user selectable) and updates the DAC output. This pin can be left floating because there is an internal pull-up resistor.
3	RESET	Active Low Reset Input. Asserting this pin returns the AD5761/AD5721 to their default power-on status where the output is clamped to ground and the output buffer is powered down. This pin can be left floating because there is an internal pull-up resistor.
4	V _{REFIN}	External Reference Voltage Input. For specified performance, V _{REFIN} = 2.5 V.
5	AGND	Ground Reference for Analog Circuitry.
6	V _{SS}	Negative Analog Supply Connection. A voltage in the range of –16.5 V to 0 V can be connected to this pin. For unipolar output ranges, connect this pin to 0 V. V _{SS} must be decoupled to AGND.
7	V _{OUT}	Analog Output Voltage of the DAC. The output amplifier is capable of directly driving a 2 kΩ, 1 nF load.
8	V _{DD}	Positive Analog Supply Connection. A voltage in the range of 4.75 V to 30 V can be connected to this pin for unipolar output ranges. Bipolar output ranges accept a voltage in the range of 4.75 V to 16.5 V. V _{DD} must be decoupled to AGND.
9	DNC	Do Not Connect. Do not connect to this pin.
10	SDO	Serial Data Output. This pin clocks data from the serial register in daisy-chain or readback mode. Data is clocked out on the rising edge of SCLK and is valid on the falling edge of SCLK.
11	LDAC	Load DAC. This logic input updates the DAC register and, consequently, the analog output. When tied permanently low, the DAC register is updated when the input register is updated. If LDAC is held high during the write to the input register, the DAC output register is not updated, and the DAC output update is held off until the falling edge of LDAC. This pin can be left floating because there is an internal pull-up resistor.
12	SDI	Serial Data Input. Data must be valid on the falling edge of SCLK.
13	SYNC	Active Low Synchronization Input. This pin is the frame synchronization signal for the serial interface. While SYNC is low, data is transferred in on the falling edge of SCLK. Data is latched on the rising edge of SYNC.
14	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of SCLK. This pin operates at clock speeds of up to 50 MHz.
15	DV _{CC}	Digital Supply. The voltage range is from 1.7 V to 5.5 V. The applied voltage sets the voltage at which the digital interface operates.
16	DGND	Digital Ground.

TERMINOLOGY

Total Unadjusted Error (TUE)

Total unadjusted error is a measure of the output error taking all the various errors into account, namely INL error, offset error, gain error, and output drift over supplies, temperature, and time. TUE is expressed in % FSR.

Relative Accuracy or Integral Nonlinearity (INL)

For the DAC, relative accuracy, or integral nonlinearity, is a measure of the maximum deviation, in LSB, from a straight line passing through the endpoints of the DAC transfer function. A typical INL error vs. DAC code plot is shown in Figure 6.

Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of ± 1 LSB maximum ensures monotonicity. This DAC is guaranteed monotonic. A typical DNL error vs. code plot is shown in Figure 10.

Monotonicity

A DAC is monotonic if the output either increases or remains constant for increasing digital input code. The [AD5761/AD5721](#) are monotonic over their full operating temperature range.

Bipolar Zero Error

Bipolar zero error is the deviation of the analog output from the ideal half-scale output of 0 V when the DAC register is loaded with 0x8000 (straight binary coding) or 0x0000 (twos complement coding) for the [AD5761/AD5721](#).

Bipolar Zero Temperature Coefficient (TC)

Bipolar zero TC is a measure of the change in the bipolar zero error with a change in temperature. It is expressed in $\mu\text{V}/^\circ\text{C}$.

Zero-Scale Error

Zero-scale error is the error in the DAC output voltage when 0x0000 (straight binary coding) or 0x8000 (twos complement coding) is loaded to the DAC register. Ideally, the output voltage is negative full scale. A plot of zero-scale error vs. temperature is shown in Figure 20.

Zero-Scale Error Temperature Coefficient (TC)

Zero-scale error TC is a measure of the change in zero-scale error with a change in temperature. It is expressed in $\mu\text{V}/^\circ\text{C}$.

Offset Error

Offset error is a measure of the difference between V_{OUT} (actual) and V_{OUT} (ideal) expressed in mV in the linear region of the transfer function.

Offset Error Temperature Coefficient (TC)

Offset error TC is a measurement of the change in offset error with a change in temperature. It is expressed in $\mu\text{V}/^\circ\text{C}$.

Gain Error

Gain error is a measure of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from the ideal expressed in % FSR. A plot of gain error vs. temperature is shown in Figure 23.

Gain Error Temperature Coefficient (TC)

Gain error TC is a measure of the change in gain error with changes in temperature. It is expressed in ppm FSR/ $^\circ\text{C}$.

DC Power Supply Rejection Ratio (DC PSRR)

DC power supply rejection ratio is a measure of the rejection of the output voltage to dc changes in the power supplies applied to the DAC. It is measured for a given dc change in power supply voltage and is expressed in mV/V.

AC Power Supply Rejection Ratio (AC PSRR)

AC power supply rejection ratio is a measure of the rejection of the output voltage to ac changes in the power supplies applied to the DAC. It is measured for a given amplitude and frequency change in power supply voltage and is expressed in decibels.

Output Voltage Settling Time

Output voltage settling time is the amount of time it takes for the output to settle to a specified level for a full-scale input change. Full-scale settling time is shown in Figure 38 to Figure 41.

Digital-to-Analog Glitch Impulse

Digital-to-analog glitch impulse is the impulse injected into the analog output when the input code in the DAC register changes state. It is normally specified as the area of the glitch in nV-sec and is measured when the digital input code is changed by 1 LSB at the major carry transition (see Figure 46 and Figure 47).

Glitch Impulse Peak Amplitude

Glitch impulse peak amplitude is the peak amplitude of the impulse injected into the analog output when the input code in the DAC register changes state. It is specified as the amplitude of the glitch in mV and is measured when the digital input code is changed by 1 LSB at the major carry transition.

Digital Feedthrough

Digital feedthrough is a measure of the impulse injected into the analog output of the DAC from the digital inputs of the DAC but is measured when the DAC output is not updated. It is specified in nV-sec and measured with a full-scale code change on the data bus.

Noise Spectral Density

Noise spectral density is a measurement of the internally generated random noise characterized as a spectral density ($\text{nV}/\sqrt{\text{Hz}}$). It is measured by loading the DAC to full scale and measuring noise at the output. It is measured in $\text{nV}/\sqrt{\text{Hz}}$. A plot of noise spectral density is shown in Figure 59.

Total Harmonic Distortion (THD)

THD is the ratio of the rms sum of harmonics to the fundamental.

For the [AD5761/AD5721](#), it is defined as

$$THD \text{ (dB)} = 20 \times \log \frac{\sqrt{V_2^2 + V_3^2 + V_4^2 + V_5^2 + V_6^2}}{V_1}$$

where:

V_1 is the rms amplitude of the fundamental.

$V_2, V_3, V_4, V_5,$ and V_6 are the rms amplitudes of the second through the sixth harmonics.

THEORY OF OPERATION

DIGITAL-TO-ANALOG CONVERTER

The AD5761/AD5721 are single channel 16-/12-bit voltage output DACs. The AD5761/AD5721 output ranges are software selectable and can be configured as follows:

- Unipolar output voltage: 0 V to 5 V, 0 V to 10 V, 0 V to 16 V, 0 V to 20 V
- Bipolar output voltage: -2.5 V to +7.5 V, ±3 V, ±5 V, ±10 V

Data is written to the AD5761/AD5721 in a 24-bit word format via a 4-wire digital interface that is serial peripheral interface (SPI) compatible. The devices also offer an SDO pin to facilitate daisy-chaining and readback.

TRANSFER FUNCTION

The input coding to the DAC can be straight binary or twos complement (bipolar ranges case only). Therefore, the transfer function is given by

$$V_{OUT} = V_{REF} \times \left[\left(M \times \frac{D}{65,536} \right) - C \right]$$

where:

V_{REF} is 2.5 V.

M is the slope for a given output range (see Table 7).

D is the decimal equivalent of the code loaded to the DAC register as follows:

0 to 4095 for the 12-bit device.

0 to 65,535 for the 16-bit device.

C is the offset for a given output range (see Table 7).

Table 7. M and C Values for Various Output Ranges

Range	M	C
±10 V	8	4
±5 V	4	2
±3 V	2.4	1.2
-2.5 V to +7.5 V	4	1
0 V to 20 V	8	0
0 V to 16 V	6.4	0
0 V to 10 V	4	0
0 V to 5 V	2	0

DAC ARCHITECTURE

The DAC architecture consists of an R/2R DAC followed by an output buffer amplifier. Figure 62 shows a block diagram of the DAC architecture. Note that the reference input is buffered prior to being applied to the DAC.

The output voltage range obtained from the configurable output amplifier is selected by writing to the 3 LSBs, (RA[2:0]), in the control register.

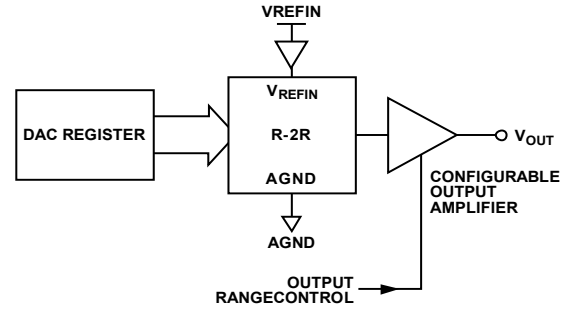

Figure 62. DAC Architecture

R/2R DAC

The architecture of the AD5761/AD5721 consists of two matched DAC sections. A simplified circuit diagram is shown in Figure 63. The six MSBs of the 16-bit data-word are decoded to drive 63 switches, E0 to E62, whereas the remaining 10 bits of the data-word drive the S0 to S9 switches of a 10-bit voltage mode R/2R ladder network.

The code loaded into the DAC register determines which arms of the ladder are switched between V_{REFIN} and ground (AGND). The output voltage is taken from the end of the ladder and amplified afterwards to provide the selected output voltage.

Figure 63. DAC Ladder Structure

Reference Buffer

The AD5761/AD5721 operate with an external reference. The reference input has an input range of 2 V to 3 V with 2.5 V for specified performance. This input voltage is then buffered before it is applied to the DAC core.

DAC Output Amplifier

The output amplifier is capable of generating both unipolar and bipolar output voltages. It is capable of driving a load of 2 kΩ in parallel with 1 nF to AGND. The source and sink capabilities of the output amplifier are shown in Figure 36.

SERIAL INTERFACE

The AD5761/AD5721 4-wire ($\overline{\text{SYNC}}$, SCLK, SDI, and SDO) digital interface is SPI compatible. The write sequence begins after bringing the $\overline{\text{SYNC}}$ line low, maintaining this line low until the complete data-word is loaded from the SDI pin. Data is loaded in at the SCLK falling edge transition (see Figure 2). When $\overline{\text{SYNC}}$ is brought high again, the serial data-word is decoded according to the instructions in Table 10. The AD5761/AD5721 contain an SDO pin to allow the user to daisy-chain multiple devices together or to read back the contents of the registers.

Standalone Operation

The serial interface works with both a continuous and noncontinuous serial clock. A continuous SCLK source can be used only when $\overline{\text{SYNC}}$ is held low for the correct number of clock cycles.

In gated clock mode, a burst clock containing the exact number of clock cycles must be used, and $\overline{\text{SYNC}}$ must be taken high after the final clock to latch the data. The first falling edge of $\overline{\text{SYNC}}$ starts the write cycle. Exactly 24 falling clock edges must be applied to SCLK before $\overline{\text{SYNC}}$ is brought high again. If $\overline{\text{SYNC}}$ is brought high before the 24th falling SCLK edge, the data written is invalid. If more than 24 falling SCLK edges are applied before $\overline{\text{SYNC}}$ is brought high, the input data is also invalid.

The input shift register is updated on the rising edge of $\overline{\text{SYNC}}$. For another serial transfer to take place, $\overline{\text{SYNC}}$ must be brought low again. After the end of the serial data transfer, data is automatically transferred from the input shift register to the addressed register. When the write cycle is complete, the output can be updated by taking LDAC low while $\overline{\text{SYNC}}$ is high.

Readback Operation

The contents of the input, DAC, and control registers can be read back via the SDO pin. Figure 4 shows how the registers are decoded. After a register has been addressed for a read, the next 24 clock cycles clock the data out on the SDO pin. The clocks must be applied while $\overline{\text{SYNC}}$ is low. When $\overline{\text{SYNC}}$ is returned high, the SDO pin is placed in tristate. For a read of a single register, the no operation (NOP) function clocks out the data. Alternatively, if more than one register is to be read, the data of the first register to be addressed clocks out at the same time that the second register to be read is being addressed. The SDO pin must be enabled to complete a readback operation. The SDO pin is enabled by default.

Daisy-Chain Operation

For systems that contain several devices, use the SDO pin to daisy chain several devices together. Daisy-chain mode is useful in system diagnostics and in reducing the number of serial interface lines. The first falling edge of $\overline{\text{SYNC}}$ starts the write cycle. SCLK is continuously applied to the input shift register when $\overline{\text{SYNC}}$ is low. If more than 24 clock pulses are applied, the data ripples out of the shift register and appears on the SDO

line. This data is clocked out on the rising edge of SCLK and is valid on the falling edge.

By connecting the SDO of the first device to the SDI input of the next device in the chain, a multidivice interface is constructed. Each device in the system requires 24 clock pulses. Therefore, the total number of clock cycles must equal $24 \times N$, where N is the total number of AD5761/AD5721 devices in the chain. When the serial transfer to all devices is complete, $\overline{\text{SYNC}}$ is taken high, which latches the input data in each device in the daisy chain and prevents any further data from being clocked into the input shift register.

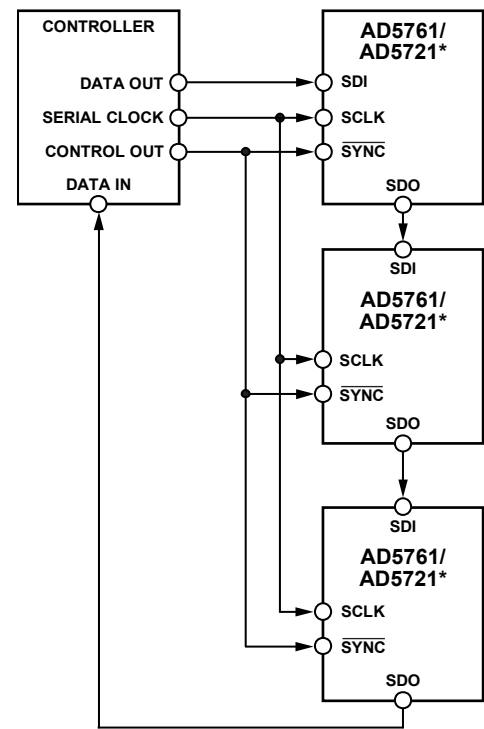

Figure 64. Daisy-Chain Block Diagram

HARDWARE CONTROL PINS

Load DAC Function ($\overline{\text{LDAC}}$)

After data transfers into the input register of the DAC, there are two ways to update the DAC register and DAC output. Depending on the status of both $\overline{\text{SYNC}}$ and $\overline{\text{LDAC}}$, one of two update modes is selected: synchronous DAC update or asynchronous DAC update.

Synchronous DAC Update

In synchronous DAC update mode, $\overline{\text{LDAC}}$ is held low while data is being clocked into the input shift register. The DAC output is updated on the rising edge of $\overline{\text{SYNC}}$.

Asynchronous DAC Update

In asynchronous DAC update mode, $\overline{\text{LDAC}}$ is held high while data is being clocked into the input shift register. The DAC output is asynchronously updated by taking $\overline{\text{LDAC}}$ low after $\overline{\text{SYNC}}$ is taken high. The update then occurs on the falling edge of $\overline{\text{LDAC}}$.

Reset Function ($\overline{\text{RESET}}$)

The AD5761/AD5721 can be reset to its power-on state by two means: either by asserting the $\overline{\text{RESET}}$ pin or by using the software full reset registers (see Table 26).

Asynchronous Clear Function ($\overline{\text{CLEAR}}$)

The $\overline{\text{CLEAR}}$ pin is a falling edge active input that allows the output to be cleared to a user defined value. The clearcode value is programmed by writing to Bit 10 and Bit 9 in the control register (see Table 11 and Table 12). It is necessary to maintain $\overline{\text{CLEAR}}$ low for a minimum amount of time to complete the operation (see Figure 2). When the $\overline{\text{CLEAR}}$ signal is returned high, the output remains at the clear value until a new value is loaded to the DAC register.

Alert Function ($\overline{\text{ALERT}}$)

When the $\overline{\text{ALERT}}$ pin is asserted low, a readback from the control register is required to clarify whether a short-circuit or brownout condition occurred, depending on the values of Bit 12 and Bit 11, SC and BO bits, respectively (see Table 15 and Table 16). If neither of these conditions occurred, the temperature exceeded approximately 150°C.

The $\overline{\text{ALERT}}$ pin is low during power-up, a software full reset, or a hardware reset. After the first write to the control register to configure the DAC, the $\overline{\text{ALERT}}$ pin is asserted high.

In the event of the die temperature exceeding approximately 150°C, the $\overline{\text{ALERT}}$ pin is low and the value of the ETS bit determines the state of the digital supply of the device, whether the internal digital supply is powered on or powered down. If the ETS bit is set to 0, the internal digital supply is powered on when the internal die temperature exceeds approximately 150°C. If the ETS bit is set to 1, the internal digital supply is powered down when the internal die temperature exceeds approximately 150°C and the device becomes nonfunctional (see Table 11 and Table 12).

The AD5761/AD5721 temperature at power-up must be less than 150°C for proper operation of the devices.

REGISTER DETAILS

INPUT SHIFT REGISTER

The input shift register is 24 bits wide. Data is loaded into the device MSB first as a 24-bit word under the control of a serial clock input, SCLK, which can operate at rates of up to 50 MHz. The input shift register consists of three don't care bits, one fixed value bit (DB20 = 0), four address bits, and a 16-bit or 12-bit data-word as shown in Table 8 and Table 9, respectively.

Table 8. AD5761 16-Bit Input Shift Register Format

CONTROL REGISTER

The control register controls the mode of operation of the AD5761/AD5721. The control register options are shown in Table 11 and Table 12.

On power-up, after a full reset, or after a hardware reset, the output of the DAC is clamped to ground through a 1 kΩ resistor and the output buffer remains in power-down mode. A write to the control register is required to configure the device, remove the clamp to ground, and power up the output buffer.

When the DAC output range is reconfigured during operation, a software full reset command (see Table 26) must be written to the device before writing to the control register.

READBACK CONTROL REGISTER

The readback control register operation provides the contents of the control register by setting the register address to 1100. Table 14 outlines the 24-bit shift register for this command, where the last 16 bits are don't care bits.

During the next command, the control register contents are shifted out of the SDO pin with the MSB shifted out first. Table 15 outlines the 24-bit data read from the SDO pin, where DB23 is the first bit shifted out.

Table 14. Readback Control Register, 24-Bit Shift Register to the SDI Pin

BO	Brownout condition. The BO bit is reset at every control register write. 0: no brownout condition detected. 1: brownout condition detected.

UPDATE DAC REGISTER FROM INPUT REGISTER

The update DAC register function loads the DAC register with the data saved in the input register, and updates the DAC output voltage. This operation is equivalent to a software LDAC. Table 17 outlines how data is written to the DAC register.

Table 17. Update DAC Register from Input Register

READBACK DAC REGISTER

The readback DAC register operation provides the contents of the DAC register by setting the register address to 1011. Table 18 outlines the 24-bit shift register for this command. During the next command, the DAC register contents are shifted out of the SDO pin with the MSB shifted out first. Table 19 outlines the 24-bit data read from the SDO pin, where DB23 is the first bit shifted out.

WRITE AND UPDATE DAC REGISTER

The write and update DAC register (Register Address 0011) updates the input register and the DAC register with the entered data-word from the input shift register, irrespective of the state of LDAC.

Setting the register address to 0001 writes the input register with the data from the input shift register, clocked in MSB first on the SDI pin.

READBACK INPUT REGISTER

The readback input register operation provides the contents of the input register by setting the register address to 1010. Table 21 outlines the 24-bit shift register for this command. During the next command, the input register contents are shifted out of the SDO pin with MSB shifted out first. Table 22 outlines the 24-bit data read from the SDO pin, where DB23 is the first bit shifted out.

¹ X means don't care.

DISABLE DAISY-CHAIN FUNCTIONALITY

The daisy-chain feature can be disabled to save the power consumed by the SDO buffer when this functionality is not required (see Table 23). When disabled, a readback request is not accepted because the SDO pin remains in tristate.

Table 23. Disable Daisy-Chain Functionality Register

Bit Name	Description
DDC	DDC decides whether daisy-chain functionality is enabled or disabled for the device. By default, daisy-chain functionality is enabled. 0: daisy-chain functionality is enabled for the device. 1: daisy-chain functionality is disabled for the device.

SOFTWARE DATA RESET

The AD5761/AD5721 can be reset via software to zero scale, midscale, or full scale (see Table 25). The value to which the device is reset is specified by the PV1 and PV0 bits, which are set in the write to control register command (see Table 11 and Table 12).

Table 25. Software Data Reset Register

MSB								LSB
DB23	DB22	DB21	DB20	DB19	DB18	DB17	DB16	DB15 to DB0
X ¹	X ¹	X ¹	0	Register address				Register data
X ¹	X ¹	X ¹	0	0111				Don't care

¹ X means don't care.

SOFTWARE FULL RESET

The device can also be reset completely via software (see Table 26). When the register address is set to 1111, the device behaves in a power-up state, where the output is clamped to AGND and the output buffer is powered down. The user must write to the control register to configure the device, remove the 1 kΩ resistor clamp to ground, and power up the output buffer.

The software full reset command is also issued when the DAC output range is reconfigured during normal operation.

APPLICATIONS INFORMATION

TYPICAL OPERATING CIRCUIT

Figure 65 shows the typical operating circuit for the AD5761/AD5721. The only external components needed for this precision 16-/12-bit DAC are decoupling capacitors on the supply pins and supply voltage. Because the AD5761/AD5721 incorporate a voltage reference and reference buffers, they eliminate the need for an external bipolar reference and associated buffers, resulting in overall savings in both cost and board space.

In Figure 65, V_{DD} is connected to 15 V and V_{SS} is connected to -15 V, but V_{DD} and V_{SS} can operate with supplies from 4.75 V to 30 V and from -16.5 V to 0 V, respectively.

Precision Voltage Reference Selection

Some applications require the use of external references to achieve the optimum performance from the AD5761/AD5721 over their full operating temperature range. Take care in the selection of the same because any error in the voltage reference is reflected in the output of the device.

There are four possible sources of error to consider when choosing a voltage reference for high accuracy applications: initial accuracy, temperature coefficient of the output voltage, long-term drift, and output voltage noise.

Initial accuracy error on the output voltage of an external reference may lead to a full-scale error in the DAC. Therefore, to minimize these errors, a reference with low initial accuracy error specification is preferred. Choosing a reference with an output trim adjustment, such as the ADR421, allows a system designer to trim system errors out by setting the reference voltage to a voltage other than the nominal. The trim adjustment can also be used at ambient temperature to trim out any error.

Long-term drift is a measure of how much the reference output voltage drifts over time. A reference with a tight long-term drift specification ensures that the overall solution remains relatively stable over its entire lifetime.

The temperature coefficient of a reference output voltage affects gain error and TUE. Choose a reference with a tight temperature coefficient specification to reduce the dependence of the DAC output voltage on ambient conditions.

In high accuracy applications, which have a relatively low noise budget, reference output voltage noise must be considered. It is important to choose a reference with as low an output noise voltage as practical for the system resolution that is required. Precision voltage references, such as the ADR4525, produce low output noise in the 0.1 Hz to 10 Hz region. However, as the

circuit bandwidth increases, filtering the output of the reference may be required to minimize the output noise.

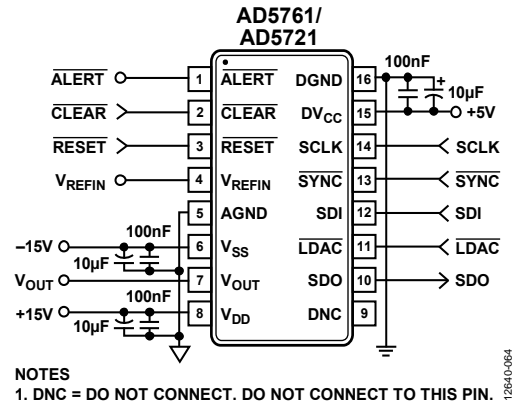

Figure 65. Typical Operating Circuit

POWER SUPPLY CONSIDERATIONS

The AD5761/AD5721 must be powered by the following three supplies to provide any of the eight output voltage ranges available on the DAC: $V_{DD} = 11$ V, $V_{SS} = -21$ V, and $DV_{CC} = 5$ V.

For applications requiring optimal high power efficiency and low noise performance, it is recommended that the ADP5070 switching regulator be used to convert the 5 V input rail into two intermediate rails (+23 V and -13 V). These intermediate rails are then postregulated by very low noise, low dropout (LDO) regulators (ADP7142 and ADP7182). Figure 66 shows the recommended method.

Figure 66. Postregulation by ADP7142 and ADP7182

EVALUATION BOARD

An evaluation board is available for the AD5761R to aid designers in evaluating the high performance of the device with minimum effort. This evaluation board can be used to evaluate the AD5761/AD5721. The AD5761R evaluation kit includes a populated and tested AD5761R printed circuit board (PCB). The evaluation board interfaces to the USB port of a PC. Software is available with the evaluation board to allow the user to easily program the AD5761R. The EVAL-AD5761RSDZ user guide gives full details on the operation of the evaluation board.

Table 28. Precision References Recommended for Use with the [AD5761/AD5721](#)

Part No.	Initial Accuracy (mV Maximum)	Long-Term Drift (ppm Typical)	Temperature Drift (ppm/°C Maximum)	0.1 Hz to 10 Hz Noise (μ V p-p Typical)
ADR03	± 2.5	50	3	6
ADR421	± 1	50	3	1.75
ADR431	± 1	40	3	3.5
ADR441	± 1	50	3	1.2
ADR4525	1	25	2	1.25
