

Fully Integrated, 8-Channel Ultrasound Analog Front End with Passive CW Mixer, 0.75 nV/rtHz, 14/12-Bit, 65 MSPS, 158 mW/CH

 : [AFE5808A](#)

FEATURES

- **8-Channel Complete Analog Front-End**
 - LNA, VCAT, PGA, LPF, ADC, and CW Mixer
- **Programmable Gain Low-Noise Amplifier (LNA)**
 - 24/18/12 dB Gain
 - 0.25/0.5/1 V_{PP} Linear Input Range
 - 0.63/0.7/0.9 nV/rtHz Input Referred Noise
 - Programmable Active Termination
- **40 dB Low Noise Voltage Controlled Attenuator (VCAT)**
- **24/30 dB Programmable Gain Amplifier (PGA)**
- **3rd Order Linear Phase Low-Pass Filter (LPF)**
 - 10, 15, 20, 30 MHz
- **14-bit Analog to Digital Converter (ADC)**
 - 77 dBFS SNR at 65 MSPS
 - LVDS Outputs
- **Noise/Power Optimizations (Full Chain)**
 - 158 mW/CH at 0.75 nV/rtHz, 65 MSPS
 - 101 mW/CH at 1.1 nV/rtHz, 40 MSPS
 - 80 mW/CH at CW Mode
- **Excellent Device-to-Device Gain Matching**
 - ±0.5 dB (Typical) and ±0.9 dB (Max)
- **Low Harmonic Distortion**
- **Fast and Consistent Overload Recovery**
- **Passive Mixer for Continuous Wave Doppler(CWD)**
 - Low Close-in Phase Noise –156 dBc/Hz at 1 KHz off 2.5 MHz Carrier
 - Phase Resolution of 1/16λ
 - Support 16X, 8X, 4X and 1X CW Clocks
 - 12dB Suppression on 3rd and 5th Harmonics
 - Flexible Input Clocks
- **Small Package: 15 mm x 9 mm, 135-BGA**

APPLICATIONS

- **Medical Ultrasound Imaging**
- **Nondestructive Evaluation Equipments**

DESCRIPTION

The AFE5808A is a highly integrated Analog Front-End (AFE) solution specifically designed for ultrasound systems in which high performance and small size are required. The AFE5808A integrates a complete time-gain-control (TGC) imaging path and a continuous wave Doppler (CWD) path. It also enables users to select one of various power/noise combinations to optimize system performance. Therefore, the AFE5808A is a suitable ultrasound analog front end solution not only for high-end systems, but also for portable ones.

The AFE5808A contains eight channels of voltage controlled amplifier (VCA), 14/12-bit Analog-to-Digital Converter (ADC), and CW mixer. The VCA includes Low noise Amplifier (LNA), Voltage controlled Attenuator (VCAT), Programmable Gain Amplifier (PGA), and Low-Pass Filter (LPF). The LNA gain is programmable to support 250 mV_{PP} to 1 V_{PP} input signals. Programmable active termination is also supported by the LNA. The ultra-low noise VCAT provides an attenuation control range of 40 dB and improves overall low gain SNR which benefits harmonic imaging and near field imaging. The PGA provides gain options of 24 dB and 30 dB. Before the ADC, a LPF can be configured as 10 MHz, 15 MHz, 20 MHz or 30 MHz to support ultrasound applications with different frequencies. The high-performance 14bit/65 MSPS ADC in the AFE5808A achieves 77dBFS SNR. It ensures excellent SNR at low chain gain. The ADC's LVDS outputs enable flexible system integration desired for miniaturized systems.

AFE5808A is an enhanced version of AFE5808 and it is recommended for new designs. Compared to AFE5808, it expands the cut-off frequency range of the digital high pass filter; increases the handling capability of extreme overload signals; lowers the correlated noise significantly when high impedance source appears.

DESCRIPTION CONTINUED

The AFE5808A also integrates a low power passive mixer and a low noise summing amplifier to accomplish on-chip CWD beamformer. 16 selectable phase-delays can be applied to each analog input signal. Meanwhile a unique 3rd and 5th order harmonic suppression filter is implemented to enhance CW sensitivity.

The AFE5808A is available in a 15mm × 9mm, 135-pin BGA package and it is specified for operation from 0°C to 85°C. It is also pin-to-pin compatible to the AFE5807 and AFE5808.

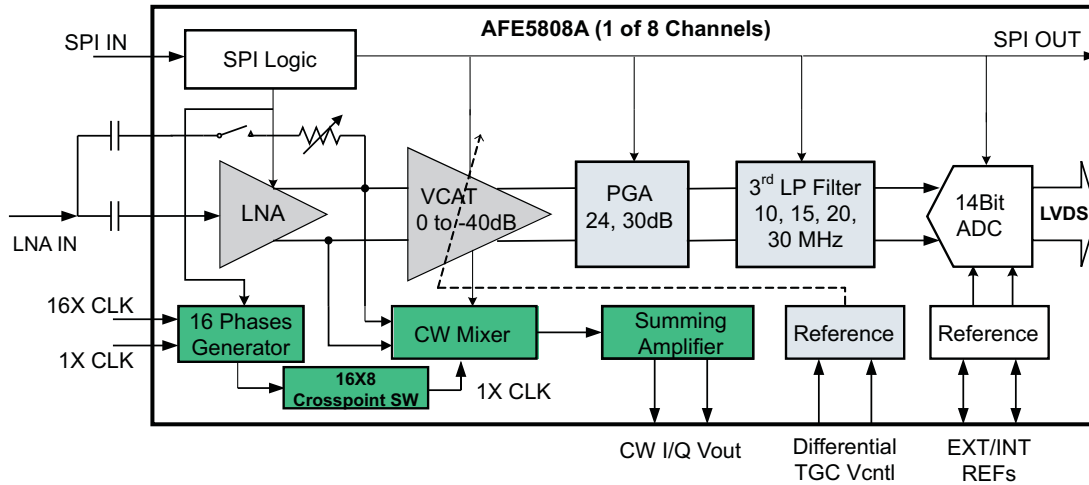

Figure 1. Block Diagram

PACKAGING/ORDERING INFORMATION⁽¹⁾⁽²⁾

PRODUCT	PACKAGE TYPE	OPERATING	ORDERING NUMBER	TRANSPORT MEDIA, QUANTITY	ECO STATUS ⁽¹⁾
AFE5808A	ZCF	0°C to 85°C	AFE5808AZCF	Tray, 160	Pb-Free, Green

- (1) For the most current package and ordering information see the Package Option Addendum at the end of this document, or see the TI web site at www.ti.com.
- (2) These packages conform to Lead (Pb)-free and green manufacturing specifications. Additional details including specific material content can be accessed at www.ti.com/leadfree. GREEN: TI defines Green to mean Lead (Pb)-Free and in addition, uses less package materials that do not contain halogens, including bromine (Br), or antimony (Sb) above 0.1% of total product weight. N/A: Not yet available Lead (Pb)-Free; for estimated conversion dates, go to www.ti.com/leadfree. Pb-FREE: TI defines Lead (Pb)-Free to mean RoHS compatible, including a lead concentration that does not exceed 0.1% of total product weight, and, if designed to be soldered, suitable for use in specified lead-free soldering processes.

ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

		VALUE	UNIT
Supply voltage range	AVDD	–0.3 to 3.9	V
	AVDD_ADC	–0.3 to 2.2	V
	AVDD_5V	–0.3 to 6	V
	DVDD	–0.3 to 2.2	V
Voltage between AVSS and LVSS		–0.3 to 0.3	V
Voltage at analog inputs and digital inputs		–0.3 to min [3.6,AVDD+0.3]	V
Peak solder temperature ⁽²⁾		260	°C
Maximum junction temperature (T _J), any condition		105	°C
Storage temperature range		–55 to 150	°C
Operating temperature range		0 to 85	°C
ESD Ratings	HBM	2000	V
	CDM	500	V

- (1) Stresses above those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute maximum rated conditions for extended periods may degrade device reliability.
- (2) Device complies with JSTD-020D.

PIN FUNCTIONS

PIN		DESCRIPTION
NO.	NAME	
B9~ B2	ACT1...ACT8	Active termination input pins for CH1~8. 1 μ F capacitors are recommended. See the Application Information section.
A1, D8, D9, E8, E9, K1	AVDD	3.3 V Analog supply for LNA, VCAT, PGA, LPF and CWD blocks.
K2	AVDD_5V	5 V Analog supply for LNA, VCAT, PGA, LPF and CWD blocks.
J6, J7, K8, L3, M1, M2	AVDD_ADC	1.8 V Analog power supply for ADC.
C1, D1~D7, E3~E7, F3~F7, G1~G7, H3~H7, J3~J5, K6	AVSS	Analog ground.
L2	CLKM_ADC	Negative input of differential ADC clock. In the single-end clock mode, it can be tied to GND directly or through a 0.1 μ F capacitor.
L1	CLKP_ADC	Positive input of differential ADC clock. In the single-end clock mode, it can be tied to clock signal directly or through a 0.1 μ F capacitor.
F9	CLKM_16X	Negative input of differential CW 16X clock. Tie to GND when the CMOS clock mode is enabled. In the 4X and 8X CW clock modes, this pin becomes the 4X or 8X CLKM input. In the 1X CW clock mode, this pin becomes the quadrature-phase 1X CLKM for the CW mixer. Can be floated if CW mode is not used.
F8	CLKP_16X	Positive input of differential CW 16X clock. In 4X and 8X clock modes, this pin becomes the 4X or 8X CLKP input. In the 1X CW clock mode, this pin becomes the quadrature-phase 1X CLKP for the CW mixer. Can be floated if CW mode is not used.
G9	CLKM_1X	Negative input of differential CW 1X clock. Tie to GND when the CMOS clock mode is enabled (Refer to Figure 89 for details). In the 1X clock mode, this pin is the In-phase 1X CLKM for the CW mixer. Can be floated if CW mode is not used.
G8	CLKP_1X	Positive input of differential CW 1X clock. In the 1X clock mode, this pin is the In-phase 1X CLKP for the CW mixer. Can be floated if CW mode is not used.
B1	CM_BYP	Bias voltage and bypass to ground. $\geq 1\mu$ F is recommended. To suppress the ultra low frequency noise, 10 μ F can be used.
E2	CW_IP_AMPINM	Negative differential input of the In-phase summing amplifier. External LPF capacitor has to be connected between CW_IP_AMPINM and CW_IP_OUTP. This pin becomes the CH7 PGA negative output when PGA test mode is enabled. Can be floated if not used.
E1	CW_IP_AMPINP	Positive differential input of the In-phase summing amplifier. External LPF capacitor has to be connected between CW_IP_AMPINP and CW_IP_OUTM. This pin becomes the CH7 PGA positive output when PGA test mode is enabled. Can be floated if not used.
F1	CW_IP_OUTM	Negative differential output for the In-phase summing amplifier. External LPF capacitor has to be connected between CW_IP_AMPINP and CW_IP_OUTM. Can be floated if not used.
F2	CW_IP_OUTP	Positive differential output for the In-phase summing amplifier. External LPF capacitor has to be connected between CW_IP_AMPINM and CW_IP_OUTP. Can be floated if not used.

PIN FUNCTIONS (continued)

PIN		DESCRIPTION
NO.	NAME	
J2	CW_QP_AMPINM	Negative differential input of the quadrature-phase summing amplifier. External LPF capacitor has to be connected between CW_QP_AMPINM and CW_QP_OUTP. This pin becomes CH8 PGA negative output when PGA test mode is enabled. Can be floated if not used.
J1	CW_QP_AMPINP	Positive differential input of the quadrature-phase summing amplifier. External LPF capacitor has to be connected between CW_QP_AMPINP and CW_QP_OUTM. This pin becomes CH8 PGA positive output when PGA test mode is enabled. Can be floated if not used.
H1	CW_QP_OUTM	Negative differential output for the quadrature-phase summing amplifier. External LPF capacitor has to be connected between CW_QP_AMPINP and CW_QP_OUTM. Can be floated if not used.
H2	CW_QP_OUTP	Positive differential output for the quadrature-phase summing amplifier. External LPF capacitor has to be connected between CW_QP_AMPINM and CW_QP_OUTP. Can be floated if not used.
N8, P9~P7, P3~P1, N2	D1M~D8M	ADC CH1~8 LVDS negative outputs
N9, R9~R7, R3~R1, N1	D1P~D8P	ADC CH1~8 LVDS positive outputs
P6	DCLKM	LVDS bit clock (7x) negative output
R6	DCLKP	LVDS bit clock (7x) positive output
K7, L5~L7,M5~M8, N4, N6	DNC	Do not connect. Must leave floated
N3, N7	DVDD	ADC digital and I/O power supply, 1.8 V
N5, P5, R5	DVSS	ADC digital ground
P4	FCLKM	LVDS frame clock (1X) negative output
R4	FCLKP	LVDS frame clock (1X) positive output
C9~C2	INM1...INM8	CH1~8 complimentary analog inputs. Bypass to ground with $\geq 0.015 \mu\text{F}$ capacitors. The HPF response of the LNA depends on the capacitors.
A9~A2	INP1...INP8	CH1~8 analog inputs. AC couple to inputs with $\geq 0.1 \mu\text{F}$ capacitors.
L8	PDN_ADC	ADC partial (fast) power down control pin with an internal pull down resistor of 100 k Ω . Active High.
J8	PDN_VCA	VCA partial (fast) power down control pin with an internal pull down resistor of 20 k Ω . Active High.
H8	PDN_GLOBAL	Global (complete) power-down control pin for the entire chip with an internal pull down resistor of 20k Ω . Active High.
L4	REFM	0.5 V reference output in the internal reference mode. Must leave floated in the internal reference mode. Adding test point on PCB is recommended for monitoring the reference output.
M4	REFP	1.5 V reference output in the internal reference mode. Must leave floated in the internal reference mode. Adding test point on PCB is recommended for monitoring the reference output.
H9	RESET	Hardware reset pin with an internal pull-down resistor of 20 k Ω . Active high.
J9	SCLK	Serial interface clock input with an internal pull-down resistor of 20k Ω
K9	SDATA	Serial interface data input with an internal pull-down resistor of 20 k Ω
M9	SDOUT	Serial interface data readout. High impedance when readout is disabled.
L9	SEN	Serial interface enable with an internal pull up resistor of 20 k Ω . Active low.
K4	VCNTLM	Negative differential attenuation control pin.
K3	VCNTLP	Positive differential attenuation control pin
K5	VHIGH	Bias voltage; bypass to ground with $\geq 1 \mu\text{F}$.
M3	VREF_IN	ADC 1.4 V reference input in the external reference mode; bypass to ground with 0.1 μF .
K7, L5~L7, M5~M8, N4, N6	DNC	Do not connect. Must leave floated

ELECTRICAL CHARACTERISTICS

AVDD_5 V = 5 V, AVDD = 3.3 V, AVDD_ADC = 1.8 V, DVDD = 1.8 V, AC-coupled with 0.1 μ F at INP and bypassed to ground with 15 nF at INM, No active termination, V_{CNTL} = 0 V, f_{IN} = 5 MHz, LNA = 18 dB, PGA = 24 dB, 14Bit, sample rate = 65 MSPS, LPF Filter = 15 MHz, low noise mode, V_{OUT} = -1 dBFS, internal 500 Ω CW feedback resistor, CMOS CW clocks, ADC configured in internal reference mode, single-ended VCNTL mode, VCNTLM = GND, at ambient temperature T_A = 25°C, unless otherwise noted. Min and max values are specified across full-temperature range with AVDD_5 V = 5 V, AVDD = 3.3 V, AVDD_ADC = 1.8 V, DVDD = 1.8 V

- (1) Noise correlation factor is defined as N_c/(N_u+N_c), where N_c is the correlated noise power in single channel; and N_u is the uncorrelated noise power in single channel. Its measurement follows the below equation, in which the SNR of single channel signal and the SNR of summed eight channel signal are measured.

$$\frac{N_C}{N_u + N_C} = \frac{\frac{10}{10} \cdot \frac{10}{10}}{\frac{10}{10} \cdot \frac{10}{10}} \times \frac{1}{56} - \frac{1}{7}$$

- (1) The DC specifications refer to the condition where the LVDS outputs are not switching, but are permanently at a valid logic level 0 or 1 with 100Ω external termination.
- (2) Setup and hold time specifications take into account the effect of jitter on the output data and clock. These specifications also assume that the data and clock paths are perfectly matched within the receiver. Any mismatch in these paths within the receiver would appear as reduced timing margins

TYPICAL CHARACTERISTICS

AVDD_5 V = 5 V, AVDD = 3.3 V, AVDD_ADC = 1.8 V, DVDD = 1.8 V, ac-coupled with 0.1 μ F caps at INP and 1 5nF caps at INM, No active termination, VCNTL = 0 V, F_{IN} = 5 MHz, LNA = 18 dB, PGA = 24 dB, 14 Bit, sample rate = 65 MSPS, LPF Filter = 15 MHz, low noise mode, V_{OUT} = -1dBFS, 500 Ω CW feedback resistor, CMOS 16X clock, ADC is configured in internal reference mode, single-ended VCNTLM = GND, at ambient temperature T_A = +25C, unless otherwise noted.

30/14bit	0.87	1.10		0.94	1.1		18.5	19.5	20.1
20/14bit	1.30	1.56		1.46	1.6		25.7	26.7	27.3

(1) FCLK timing is the same as for the output data lines. It has the same relation to DCLK as the data pins. Setup and hold are the same for the data and the frame clock.

(2) Data valid is logic HIGH = +100mV and logic LOW = -100mV

(3) Timing parameters are ensured by design and characterization; not production tested.

12-Bit 6x serialization mode

14-Bit 7x serialization mode

Figure 59. LVDS Timing Diagrams

LVDS Output Interface Description

AFE5808A has LVDS output interface which supports multiple output formats. The ADC resolutions can be configured as 12bit or 14bit as shown in the LVDS timing diagrams [Figure 59](#). The ADCs in the AFE5808A are running at 14bit; 2 LSBs are removed when 12-bit output is selected; and two 0s are added at LSBs when 16-bit output is selected. Appropriate ADC resolutions can be selected for optimizing system performance-cost effectiveness. When the devices run at 16bit mode, higher end FPGAs are required to process higher rate of LVDS data. Corresponding register settings are listed in [Table 1](#).

Table 1. Corresponding Register Settings

LVDS Rate	12 bit (6X DCLK)	14 bit (7X DCLK)	16 bit (8X DCLK)
Reg 3 [14:13]	11	00	01
Reg 4 [2:0]	010	000	000
Description	2 LSBs removed	N/A	2 0s added at LSBs

SERIAL REGISTER TIMING

Serial Register Write Description

Programming of different modes can be done through the serial interface formed by pins SEN (serial interface enable), SCLK (serial interface clock), SDATA (serial interface data) and RESET. All these pins have a pull-down resistor to GND of 100kΩ. Serial shift of bits into the device is enabled when SEN is low. Serial data SDATA is latched at every rising edge of SCLK when SEN is active (low). The serial data is loaded into the register at every 24th SCLK rising edge when SEN is low. If the word length exceeds a multiple of 24 bits, the excess bits are ignored. Data can be loaded in multiple of 24-bit words within a single active SEN pulse (there is an internal counter that counts groups of 24 clocks after the falling edge of SEN). The interface can work with the SCLK frequency from 20 MHz down to low speeds (few Hertz) and even with non-50% duty cycle SCLK. The data is divided into two main portions: a register address (8 bits) and the data itself (16 bits), to load on the addressed register. When writing to a register with unused bits, these should be set to 0. [Figure 60](#) illustrates this process.

T0384-01

Figure 60. SPI Timing

SPI Timing Characteristics

Minimum values across full temperature range $T_{MIN} = 0^{\circ}C$ to $T_{MAX} = 85^{\circ}C$, $AVDD_{5V} = 5.0V$, $AVDD = 3.3V$, $AVDD_{ADC} = 1.8V$, $DVDD = 1.8V$

PARAMETER	DESCRIPTION	MIN	TYP	MAX	UNIT
t_1	SCLK period	50			ns
t_2	SCLK high time	20			ns
t_3	SCLK low time	20			ns
t_4	Data setup time	5			ns
t_5	Data hold time	5			ns
t_6	\overline{SEN} fall to SCLK rise	8			ns
t_7	Time between last SCLK rising edge to \overline{SEN} rising edge	8			ns
t_8	SDOUT delay	12	20	28	ns

Register Readout

The device includes an option where the contents of the internal registers can be read back. This may be useful as a diagnostic test to verify the serial interface communication between the external controller and the AFE. First, the <REGISTER READOUT ENABLE> bit (Reg0[1]) needs to be set to '1'. Then user should initiate a serial interface cycle specifying the address of the register (A7-A0) whose content has to be read. The data bits are "don't care". The device will output the contents (D15-D0) of the selected register on the SDOOUT pin. SDOOUT has a typical delay t_8 of 20nS from the falling edge of the SCLK. For lower speed SCLK, SDOOUT can be latched on the rising edge of SCLK. For higher speed SCLK, e.g. the SCLK period lesser than 60nS, it would be better to latch the SDOOUT at the next falling edge of SCLK. The following timing diagram shows this operation (the time specifications follow the same information provided. In the readout mode, users still can access the <REGISTER READOUT ENABLE> through SDATA/SCLK/ \overline{SEN} . To enable serial register writes, set the <REGISTER READOUT ENABLE> bit back to '0'.

Figure 61. Serial Interface Register Read

The AFE5808A SDOOUT buffer is tri-stated and will get enabled only when 0[1] (REGISTER READOUT ENABLE) is enabled. SDOOUT pins from multiple AFE5808As can be tied together without any pull-up resistors. Level shifter SN74AUP1T04 can be used to convert 1.8V logic to 2.5V/3.3V logics if needed.

$10 \mu\text{s} < t_1 < 50 \text{ ms}$, $10 \mu\text{s} < t_2 < 50 \text{ ms}$, $-10 \text{ ms} < t_3 < 10 \text{ ms}$, $t_4 > 10 \text{ ms}$, $t_5 > 100 \text{ ns}$, $t_6 > 100 \text{ ns}$, $t_7 > 10 \text{ ms}$, and $t_8 > 100 \mu\text{s}$.

The AVDDx and DVDD power-on sequence does not matter as long as $-10\text{ms} < t_3 < 10\text{ms}$. Similar considerations apply while shutting down the device.

Figure 62. Recommended Power-up Sequencing and Reset Timing

REGISTER MAP

ADC Register Map

A reset process is required at the AFE5808A initialization stage. Initialization can be done in one of two ways:

1. Through a hardware reset, by applying a positive pulse in the RESET pin
2. Through a software reset, using the serial interface, by setting the SOFTWARE RESET bit to high. Setting this bit initializes the internal registers to the respective default values (all zeros) and then self-resets the SOFTWARE RESET bit to low. In this case, the RESET pin can stay low (inactive).

After reset, all ADC and VCA registers are set to '0', i.e. default settings. During register programming, all reserved/unlisted register bits need to be set as '0'. Register settings are maintained when the AFE5808A is in either partial power down mode or complete power down mode.

Table 2. ADC Register Map

ADDRESS (DEC)	ADDRESS (HEX)	Default Value	FUNCTION	DESCRIPTION
0[0]	0x0[0]	0	SOFTWARE_RESET	0: Normal operation; 1: Resets the device and self-clears the bit to '0'
0[1]	0x0[1]	0	REGISTER_READOUT_ENABLE	0: Disables readout; 1: enables readout of register at SDOOUT Pin
1[0]	0x1[0]	0	ADC_COMPLETE_PDN	0: Normal 1: Complete Power down
1[1]	0x1[1]	0	LVDS_OUTPUT_DISABLE	0: Output Enabled; 1: Output disabled
1[9:2]	0x1[9:2]	0	ADC_PDN_CH<7:0>	0: Normal operation; 1: Power down. Power down Individual ADC channels. 1[9]→CH8...1[2]→CH1
1[10]	0x1[10]	0	PARTIAL_PDN	0: Normal Operation; 1: Partial Power Down ADC
1[11]	0x1[11]	0	LOW_FREQUENCY_NOISE_SUPPRESSION	0: No suppression; 1: Suppression Enabled
1[13]	0x1[13]	0	EXT_REF	0: Internal Reference; 1: External Reference. VREF_IN is used. Both 3[15] and 1[13] should be set as 1 in the external reference mode
1[14]	0x1[14]	0	LVDS_OUTPUT_RATE_2X	0: 1x rate; 1: 2x rate. Combines data from 2 channels on 1 LVDS pair. When ADC clock rate is low, this feature can be used
1[15]	0x1[15]	0	SINGLE-ENDED_CLK_MODE	0: Differential clock input; 1: Single-ended clock input

29[9:0]	0x1D[9:0]	0	OFFSET_CH6	value to be subtracted from channel 6 code
29[15:11]	0x1D[15:11]	0	DIGITAL_GAIN_CH6	0 dB to 6 dB in 0.2 dB steps
31[9:0]	0x1F[9:0]	0	OFFSET_CH5	value to be subtracted from channel 5 code
31[15:11]	0x1F[15:11]	0	DIGITAL_GAIN_CH5	0 dB to 6 dB in 0.2 dB steps
33[0]	0x21[0]	0	DIGITAL_HPF_FILTER_ENABLE_CH5-8	0: Disable the digital HPF filter; 1: Enable for 5-8 channels
33[4:1]	0x21[4:1]	0	DIGITAL_HPF_FILTER_K_CH5-8	Set K for the high-pass filter (k from 2 to 10, 010B to 1010B) This group of four registers controls the characteristics of a digital high-pass transfer function applied to the output data, following the formula: $y(n) = 2^k / (2^k + 1) [x(n) - x(n-1) + y(n-1)]$ (see Table 3 and Figure 58)
66[15]	0x42[15]	0	DITHER	0: Disable dither function. 1: Enable dither function. Improve the ADC linearity with slight noise degradation.

ADC Register/Digital Processing Description

The ADC in the AFE5808A has extensive digital processing functionalities which can be used to enhance ultrasound system performance. The digital processing blocks are arranged as in [Figure 63](#).

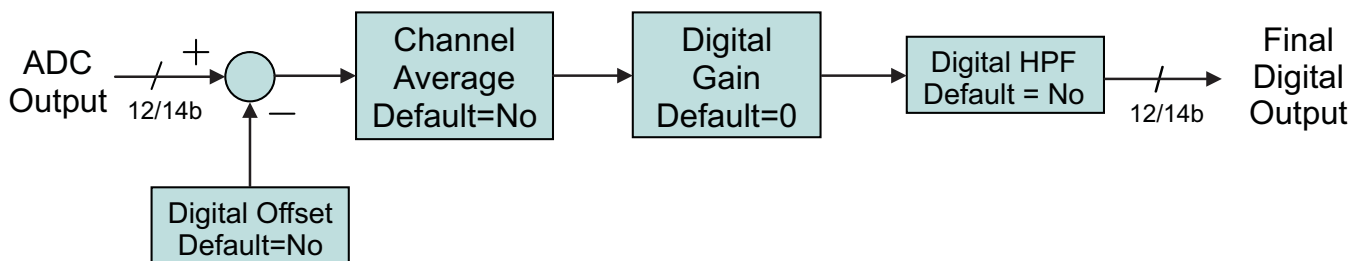

Figure 63. ADC Digital Block Diagram

AVERAGING_ENABLE: Address: 2[11]

When set to 1, two samples, corresponding to two consecutive channels, are averaged (channel 1 with 2, 3 with 4, 5 with 6, and 7 with 8). If both channels receive the same input, the net effect is an improvement in SNR. The averaging is performed as:

- Channel 1 + channel 2 comes out on channel 3
- Channel 3 + channel 4 comes out on channel 4
- Channel 5 + channel 6 comes out on channel 5
- Channel 7 + channel 8 comes out on channel 6

ADC_OUTPUT_FORMAT: Address: 4[3]

The ADC output, by default, is in 2's-complement mode. Programming the ADC_OUTPUT_FORMAT bit to 1 inverts the MSB, and the output becomes straight-offset binary mode.

DIGITAL_GAIN_ENABLE: Address: 3[12]

Setting this bit to 1 applies to each channel i the corresponding gain given by DIGITAL_GAIN_CHi <15:11>. The gain is given as $0\text{dB} + 0.2\text{dB} \times \text{DIGITAL_GAIN_CHi}<15:11>$. For instance, if DIGITAL_GAIN_CH5<15:11> = 3, channel 5 is increased by 0.6dB gain. DIGITAL_GAIN_CHi <15:11> = 31 produces the same effect as DIGITAL_GAIN_CHi <15:11> = 30, setting the gain of channel i to 6dB.

DIGITAL_HPF_ENABLE

- CH1-4: Address 21[0]
- CH5-8: Address 33[0]

DIGITAL_HPF_FILTER_K_CHX

- CH1-4: Address 21[4:1]
- CH5-8: Address 3[4:1]

This group of registers controls the characteristics of a digital high-pass transfer function applied to the output data, following [Equation 1](#).

$$y(n) = \frac{2^k}{2^k + 1} [x(n) - x(n-1) + y(n-1)] \quad (1)$$

These digital HPF registers (one for the first four channels and one for the second group of four channels) describe the setting of K . The digital high pass filter can be used to suppress low frequency noise which commonly exists in ultrasound echo signals. The digital filter can significantly benefit near field recovery time due to T/R switch low frequency response. [Table 3](#) shows the cut-off frequency vs K , also see [Figure 58](#).

Table 3. Digital HPF –1dB Corner Frequency vs K and Fs

k	40 MSPS	50 MSPS	65 MSPS
2	278 KHz	348 KHz	452 KHz
3	149 KHz	186 KHz	242 KHz
4	77 KHz	96 KHz	125 KHz

LOW_FREQUENCY_NOISE_SUPPRESSION: Address: 1[11]

The low-frequency noise suppression mode is especially useful in applications where good noise performance is desired in the frequency band of 0MHz to 1MHz (around dc). Setting this mode shifts the low-frequency noise of the AFE5808A to approximately $F_s/2$, thereby moving the noise floor around dc to a much lower value. Register bit 1[11] is used for enabling or disabling this feature. When this feature is enabled, power consumption of the device will be increased by approximate 1 mW/CH.

LVDS_OUTPUT_RATE_2X: Address: 1[14]

The output data always uses a DDR format, with valid/different bits on the positive as well as the negative edges of the LVDS bit clock, DCLK. The output rate is set by default to 1X (LVDS_OUTPUT_RATE_2X = 0), where each ADC has one LVDS stream associated with it. If the sampling rate is low enough, two ADCs can share one LVDS stream, in this way lowering the power consumption devoted to the interface. The unused outputs will output zero. To avoid consumption from those outputs, no termination should be connected to them. The distribution on the used output pairs is done in the following way:

- Channel 1 and channel 2 come out on channel 3. Channel 1 comes out first.
- Channel 3 and channel 4 come out on channel 4. Channel 3 comes out first.
- Channel 5 and channel 6 come out on channel 5. Channel 5 comes out first.
- Channel 7 and channel 8 come out on channel 6. Channel 7 comes out first

CHANNEL_OFFSET_SUBTRACTION_ENABLE: Address: 3[8]

Setting this bit to 1 enables the subtraction of the value on the corresponding OFFSET_CHx<9:0> (offset for channel i) from the ADC output. The number is specified in 2s-complement format. For example, OFFSET_CHx<9:0> = 00 0100 0000 means subtract –128. For OFFSET_CHx<9:0> = 00 0111 1111 the effect is to subtract 127. In effect, both addition and subtraction can be performed. Note that the offset is applied before the digital gain (see DIGITAL_GAIN_ENABLE). The whole data path is 2s-complement throughout internally, with digital gain being the last step. Only when DFS = 1 (straight binary output format) is the 2s-complement word translated into offset binary at the end.

SERIALIZED_DATA_RATE: Address: 3[14:13]

See [Table 1](#) for detail description.

TEST_PATTERN_MODES: Address: 2[15:13]

The AFE5808A can output a variety of test patterns on the LVDS outputs. These test patterns replace the normal ADC data output. The device may also be made to output 6 preset patterns:

1. **Ramp:** Setting Register 2[15:13]=111 causes all the channels to output a repeating full-scale ramp pattern. The ramp increments from zero code to full-scale code in steps of 1LSB every clock cycle. After hitting the full-scale code, it returns back to zero code and ramps again.
2. **Zeros:** The device can be programmed to output all zeros by setting Register 2[15:13]=110;
3. **Ones:** The device can be programmed to output all 1s by setting Register 2[15:13]=100;
4. **Deskew Patten:** When 2[15:13]=010; this mode replaces the 14-bit ADC output with the 01010101010101 word.
5. **Sync Pattern:** When 2[15:13]=001, the normal ADC output is replaced by a fixed 111111110000000 word.
6. **Toggle:** When 2[15:13]=101, the normal ADC output is alternating between 1's and 0's. The start state of ADC word can be either 1's or 0's.
7. **Custom Pattern:** It can be enabled when 2[15:13]= 011;. Users can write the required VALUE into register bits <CUSTOM PATTERN> which is Register 5[13:0]. Then the device will output VALUE at its outputs, about 3 to 4 ADC clock cycles after the 24th rising edge of SCLK. So, the time taken to write one value is 24

SCLK clock cycles + 4 ADC clock cycles. To change the customer pattern value, users can repeat writing Register 5[13:0] with a new value. Due to the speed limit of SPI, the refresh rate of the custom pattern may not be high. For example, 128 points custom pattern will take approximately $128 \times (24 \text{ SCLK clock cycles} + 4 \text{ ADC clock cycles})$.

NOTE

only one of the above patterns can be active at any given instant.

SYNC_PATTERN: Address: 10[8]

By enabling this bit, all channels' test pattern outputs are synchronized. When 10[8] is set as 1, the ramp patterns of all 8 channels start simultaneously.

VCA Register Map

Table 4. VCA Register Map

ADDRESS (DEC)	ADDRESS (HEX)	Default Value	FUNCTION	DESCRIPTION
51[0]	0x33[0]	0	RESERVED	0
51[3:1]	0x33[3:1]	0	LPF_PROGRAMMABILITY	000: 15MHz, 010: 20MHz, 011: 30MHz, 100: 10MHz
51[4]	0x33[4]	0	PGA_INTEGRATOR_DISABLE (PGA_HPF_DISABLE)	0: Enable 1: Disables offset integrator for PGA. See explanation for the PGA integrator function in APPLICATION INFORMATION section
51[6:5]	0x33[6:5]	0	PGA_CURRENT_CLAMP_LEVEL	00: -2dBFS; 10: 0dBFS; 01: -4dBFS when 51[7]=0 Note: the current clamp circuit makes sure that PGA output is in linear range. For example, at 00 setting, PGA output HD3 will be worsen by 3dB at -2dBFS ADC input. In normal operation, the current clamp function can be set as 00
51[7]	0x33[7]	0	PGA_CURRENT_CLAMP_DISABLE	0: Enables the PGA current clamp circuit; 1: Disables the PGA current clamp circuit before the PGA outputs. 51[6:5] determines the current clamp level
51[13]	0x33[13]	0	PGA_GAIN_CONTROL	0: 24dB; 1: 30dB.
52[4:0]	0x34[4:0]	0	ACTIVE_TERMINATION_ INDIVIDUAL_RESISTOR_CNTL	See Table 6 Reg 52[5] should be set as '1' to access these bits
52[5]	0x34[5]	0	ACTIVE_TERMINATION_ INDIVIDUAL_RESISTOR_ENABLE	0: Disables; 1: Enables internal active termination individual resistor control
52[7:6]	0x34[7:6]	0	PRESET_ACTIVE_TERMINATIONS	00: 50ohm, 01: 100ohm, 10: 200ohm, 11: 400ohm. (Note: the device will adjust resistor mapping (52[4:0]) automatically. 50ohm active termination is NOT supported in 12dB LNA setting. Instead, '00' represents high impedance mode when LNA gain is 12dB)
52[8]	0x34[8]	0	ACTIVE_TERMINATION_ENABLE	0: Disables; 1: Enables active termination
52[10:9]	0x34[10:9]	0	LNA_INPUT_CLAMP_SETTING	00: Auto setting, 01: 1.5Vpp, 10: 1.15Vpp and 11: 0.6Vpp
52[11]	0x34[11]	0	RESERVED	Set to 0

AFE5808A VCA Register Description

LNA Input Impedances Configuration (Active Termination Programmability)

Different LNA input impedances can be configured through the register 52[4:0]. By enabling and disabling the feedback resistors between LNA outputs and ACTx pins, LNA input impedance is adjustable accordingly. [Table 5](#) describes the relationship between LNA gain and 52[4:0] settings. The input impedance settings are the same for both TGC and CW paths.

The AFE5808A also has 4 preset active termination impedances as described in 52[7:6]. An internal decoder is used to select appropriate resistors corresponding to different LNA gain.

Table 5. Register 52[4:0] Description

52[4:0]/0x34[4:0]	FUNCTION
00000	No feedback resistor enabled
00001	Enables 450 Ω feedback resistor
00010	Enables 900 Ω feedback resistor
00100	Enables 1800 Ω feedback resistor
01000	Enables 3600 Ω feedback resistor
10000	Enables 4500 Ω feedback resistor

Programmable Gain for CW Summing Amplifier

Different gain can be configured for the CW summing amplifier through the register 54[4:0]. By enabling and disabling the feedback resistors between the summing amplifier inputs and outputs, the gain is adjustable accordingly to maximize the dynamic range of CW path. [Table 7](#) describes the relationship between the summing amplifier gain and 54[4:0] settings.

Table 7. Register 54[4:0] Description

Programmable Phase Delay for CW Mixer

Accurate CW beamforming is achieved through adjusting the phase delay of each channel. In the AFE5808A, 16 different phase delays can be applied to each LNA output; and it meets the standard requirement of typical $\frac{1}{16}\lambda$ ultrasound beamformer, i.e. $\frac{1}{16}\lambda$ beamformer resolution. [Table 7](#) describes the relationship between the phase delays and the register 55 and 56 settings.

THEORY OF OPERATION

AFE5808A OVERVIEW

The AFE5808A is a highly integrated Analog Front-End (AFE) solution specifically designed for ultrasound systems in which high performance and small size are required. The AFE5808A integrates a complete time-gain-control (TGC) imaging path and a continuous wave Doppler (CWD) path. It also enables users to select one of various power/noise combinations to optimize system performance. The AFE5808A contains eight channels; each channel includes a Low-Noise Amplifier (LNA), a Voltage Controlled Attenuator (VCAT), a Programmable Gain Amplifier (PGA), a Low-pass Filter (LPF), a 14-bit Analog-to-Digital Converter (ADC), and a CW mixer.

In addition, multiple features in the AFE5808A are suitable for ultrasound applications, such as active termination, individual channel control, fast power up/down response, programmable clamp voltage control, fast and consistent overload recovery, etc. Therefore the AFE5808A brings premium image quality to ultra-portable, handheld systems all the way up to high-end ultrasound systems. Its simplified function block diagram is listed in Figure 64.

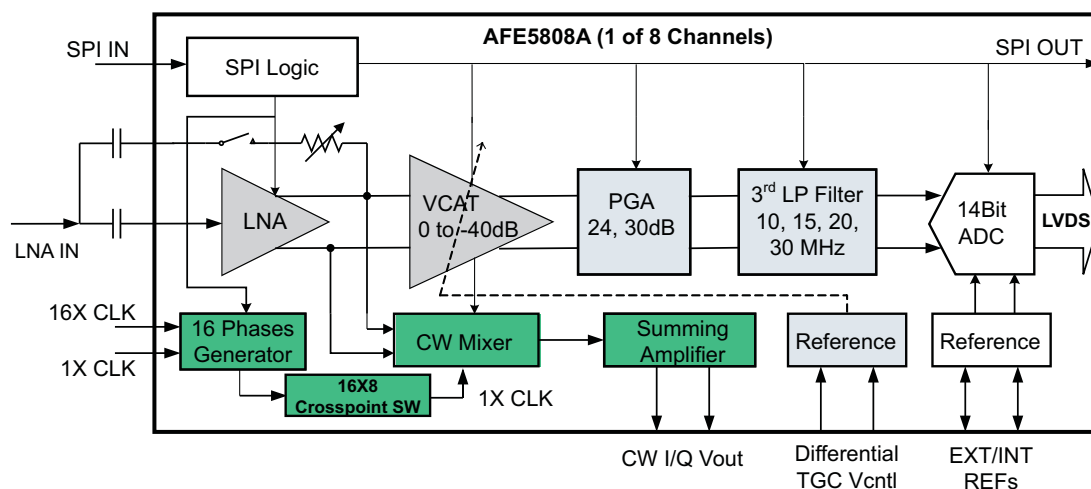

Figure 64. Functional Block Diagram

LOW-NOISE AMPLIFIER (LNA)

In many high-gain systems, a low noise amplifier is critical to achieve overall performance. Using a new proprietary architecture, the LNA in the AFE5808A delivers exceptional low-noise performance, while operating on a low quiescent current compared to CMOS-based architectures with similar noise performance. The LNA performs single-ended input to differential output voltage conversion. It is configurable for a programmable gain of 24/18/12dB and its input-referred noise is only 0.63/0.70/0.9nV/ $\sqrt{\text{Hz}}$ respectively. Programmable gain settings result in a flexible linear input range up to 1Vpp, realizing high signal handling capability demanded by new transducer technologies. Larger input signal can be accepted by the LNA; however the signal can be distorted since it exceeds the LNA's linear operation region. Combining the low noise and high input range, a wide input dynamic range is achieved consequently for supporting the high demands from various ultrasound imaging modes.

The LNA input is internally biased at approximately +2.4V; the signal source should be ac-coupled to the LNA input by an adequately-sized capacitor, e.g. $\geq 0.1\mu\text{F}$. To achieve low DC offset drift, the AFE5808A incorporates a DC offset correction circuit for each amplifier stage. To improve the overload recovery, an integrator circuit is used to extract the DC component of the LNA output and then fed back to the LNA's complementary input for DC offset correction. This DC offset correction circuit has a high-pass response and can be treated as a high-pass filter. The effective corner frequency is determined by the capacitor C_{BYPASS} connected at INM. With larger capacitors, the corner frequency is lower. For stable operation at the highest HP filter cut-off frequency, a $\geq 15\text{nF}$ capacitor can be selected. This corner frequency scales almost linearly with the value of the C_{BYPASS} . For example, 15nF gives a corner frequency of approximately 100 kHz, while 47nF can give an effective corner frequency of 33 KHz. The DC offset correction circuit can also be disabled/enabled through register 52[12].

The AFE5808A can be terminated passively or actively. Active termination is preferred in ultrasound application for reducing reflection from mismatches and achieving better axial resolution without degrading noise figure too much. Active termination values can be preset to 50, 100, 200, 400Ω; other values also can be programmed by users through register 52[4:0]. A feedback capacitor is required between ACTx and the signal source as [Figure 65](#) shows. On the active termination path, a clamping circuit is also used to create a low impedance path when overload signal is seen by the AFE5808A. The clamp circuit limits large input signals at the LNA inputs and improves the overload recovery performance of the AFE5808A. The clamp level can be set to 350mVpp, 600mVpp, 1.15Vpp automatically depending on the LNA gain settings when register 52[10:9]=0. Other clamp voltages, such as 1.15Vpp, 0.6Vpp, and 1.5Vpp, are also achievable by setting register 52[10:9]. This clamping circuit is also designed to obtain good pulse inversion performance and reduce the impact from asymmetric inputs.

Figure 65. AFE5808A LNA with DC Offset Correction Circuit

VOLTAGE-CONTROLLED ATTENUATOR

The voltage-controlled attenuator is designed to have a linear-in-dB attenuation characteristic; that is, the average gain loss in dB (refer to [Figure 2](#)) is constant for each equal increment of the control voltage (VCNTL) as shown in [Figure 66](#). A differential control structure is used to reduce common mode noise. A simplified attenuator structure is shown in the following [Figure 66](#) and [Figure 67](#).

The attenuator is essentially a variable voltage divider that consists of the series input resistor (RS) and seven shunt FETs placed in parallel and controlled by sequentially activated clipping amplifiers (A1 through A7). VCNTL is the effective difference between VCNTLP and VCNTLM. Each clipping amplifier can be understood as a specialized voltage comparator with a soft transfer characteristic and well-controlled output limit voltage. Reference voltages V1 through V7 are equally spaced over the 0V to 1.5V control voltage range. As the control voltage increases through the input range of each clipping amplifier, the amplifier output rises from a voltage where the FET is nearly OFF to VHIGH where the FET is completely ON. As each FET approaches its ON state and the control voltage continues to rise, the next clipping amplifier/FET combination takes over for the next portion of the piecewise-linear attenuation characteristic. Thus, low control voltages have most of the FETs turned OFF, producing minimum signal attenuation. Similarly, high control voltages turn the FETs ON, leading to maximum signal attenuation. Therefore, each FET acts to decrease the shunt resistance of the voltage divider formed by RS and the parallel FET network.

Additionally, a digitally controlled TGC mode is implemented to achieve better phase-noise performance in the AFE5808A. The attenuator can be controlled digitally instead of the analog control voltage VCNTL. This mode can be set by the register bit 59[7]. The variable voltage divider is implemented as a fixed series resistance and FET as the shunt resistance. Each FET can be turned ON by connecting the switches SW1-7. Turning on each of the switches can give approximately 6dB of attenuation. This can be controlled by the register bits 59[6:4]. This digital control feature can eliminate the noise from the VCNTL circuit and ensure the better SNR and phase noise for TGC path.

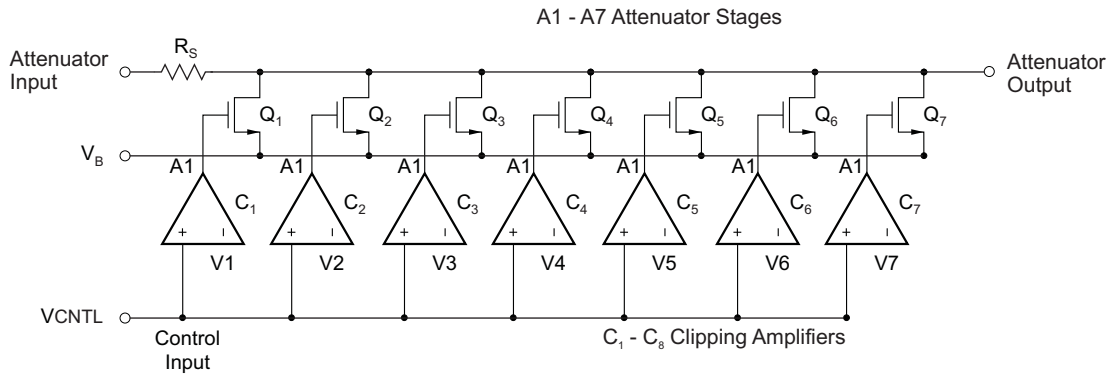

Figure 66. Simplified Voltage Controlled Attenuator (Analog Structure)

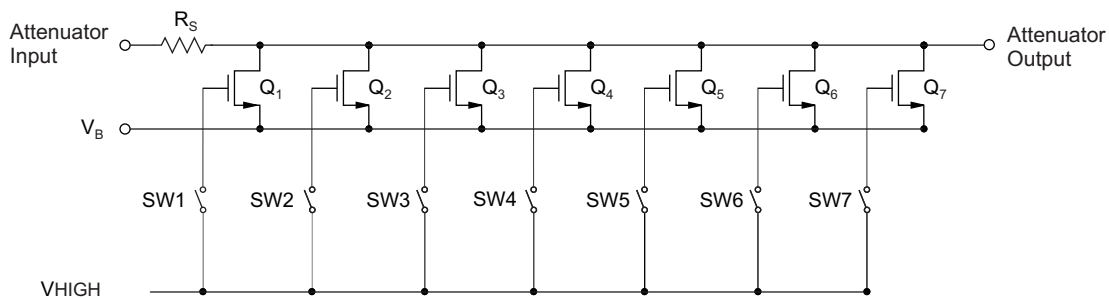

Figure 67. Simplified Voltage Controlled Attenuator (Digital Structure)

The voltage controlled attenuator’s noise follows a monotonic relationship to the attenuation coefficient. At higher attenuation, the input-referred noise is higher and vice-versa. The attenuator’s noise is then amplified by the PGA and becomes the noise floor at ADC input. In the attenuator’s high attenuation operating range, i.e. VCNTL is high, the attenuator’s input noise may exceed the LNA’s output noise; the attenuator then becomes the dominant noise source for the following PGA stage and ADC. Therefore the attenuator’s noise should be minimized compared to the LNA output noise. The AFE5808A’s attenuator is designed for achieving low noise even at high attenuation (low channel gain) and realizing better SNR in near field. The input referred noise for different attenuations is listed in the below table:

Table 10. Voltage-Controlled-Attenuator noise vs Attenuation

Attenuation (dB)	Attenuator Input Referred noise (nV/rtHz)
-40	10.5
-36	10
-30	9
-24	8.5
-18	6
-12	4
-6	3
0	2

PROGRAMMABLE GAIN AMPLIFIER (PGA)

After the voltage controlled attenuator, a programmable gain amplifier can be configured as 24dB or 30dB with a constant input referred noise of 1.75 nV/rtHz. The PGA structure consists of a differential voltage-to-current converter with programmable gain, current clamp(bias control) circuits, a transimpedance amplifier with a programmable low-pass filter, and a DC offset correction circuit. Its simplified block diagram is shown below:

Figure 68. Simplified Block Diagram of PGA

Low input noise is always preferred in a PGA and its noise contribution should not degrade the ADC SNR too much after the attenuator. At the minimum attenuation (used for small input signals), the LNA noise dominates; at the maximum attenuation (large input signals), the PGA and ADC noise dominates. Thus 24 dB gain of PGA achieves better SNR as long as the amplified signals can exceed the noise floor of the ADC.

The PGA current clamp circuit can be enabled (register 51) to improve the overload recovery performance of the AFE. If we measure the standard deviation of the output just after overload, for $0.5\text{ V } V_{\text{CNTL}}$, it is about 3.2 LSBs in normal case, i.e the output is stable in about 1 clock cycle after overload. With the current clamp circuit disabled, the value approaches 4 LSBs meaning a longer time duration before the output stabilizes; however, with the current clamp circuit enabled, there will be degradation in HD3 for PGA output levels $> -2\text{dBFS}$. For example, for a -2dBFS output level, the HD3 degrades by approximately 3dB.

The AFE5808A integrates an anti-aliasing filter in the form of a programmable low-pass filter (LPF) in the transimpedance amplifier. The LPF is designed as a differential, active, 3rd order filter with a typical 18dB per octave roll-off. Programmable through the serial interface, the -1dB frequency corner can be set to one of 10MHz, 15 MHz, 20 MHz, and 30MHz. The filter bandwidth is set for all channels simultaneously.

A selectable DC offset correction circuit is implemented in the PGA as well. This correction circuit is similar to the one used in the LNA. It extracts the DC component of the PGA outputs and feeds back to the PGA's complimentary inputs for DC offset correction. This DC offset correction circuit also has a high-pass response with a cut-off frequency of 80 KHz.

ANALOG TO DIGITAL CONVERTER

The analog-to-digital converter (ADC) of the AFE5808A employs a pipelined converter architecture that consists of a combination of multi-bit and single-bit internal stages. Each stage feeds its data into the digital error correction logic, ensuring excellent differential linearity and no missing codes at the 14-bit level. The 14 bits given out by each channel are serialized and sent out on a single pair of pins in LVDS format. All eight channels of the AFE5808A operate from a common input clock (CLKP/M). The sampling clocks for each of the eight channels are generated from the input clock using a carefully matched clock buffer tree. The 14x clock required for the serializer is generated internally from the CLKP/M pins. A 7x and a 1x clock are also given out in LVDS format, along with the data, to enable easy data capture. The AFE5808A operates from internally-generated reference voltages that are trimmed to improve the gain matching across devices. The nominal values of REFP and REFM are 1.5V and 0.5V, respectively. Alternately, the device also supports an external reference mode that can be enabled using the serial interface.

Using serialized LVDS transmission has multiple advantages, such as a reduced number of output pins (saving routing space on the board), reduced power consumption, and reduced effects of digital noise coupling to the analog circuit inside the AFE5808A.

CONTINUOUS-WAVE (CW) BEAMFORMER

Continuous-wave Doppler is a key function in mid-end to high-end ultrasound systems. Compared to the TGC mode, the CW path needs to handle high dynamic range along with strict phase noise performance. CW beamforming is often implemented in analog domain due to the mentioned strict requirements. Multiple beamforming methods are being implemented in ultrasound systems, including passive delay line, active mixer, and passive mixer. Among all of them, the passive mixer approach achieves optimized power and noise. It satisfies the CW processing requirements, such as wide dynamic range, low phase noise, accurate gain and phase matching.

A simplified CW path block diagram and an In-phase or Quadrature (I/Q) channel block diagram are illustrated below respectively. Each CW channel includes a LNA, a voltage-to-current converter, a switch-based mixer, a shared summing amplifier with a low-pass filter, and clocking circuits. All blocks include well-matched in-phase and quadrature channels to achieve good image frequency rejection as well as beamforming accuracy. As a result, the image rejection ratio from an I/Q channel is better than -46dBc which is desired in ultrasound systems.

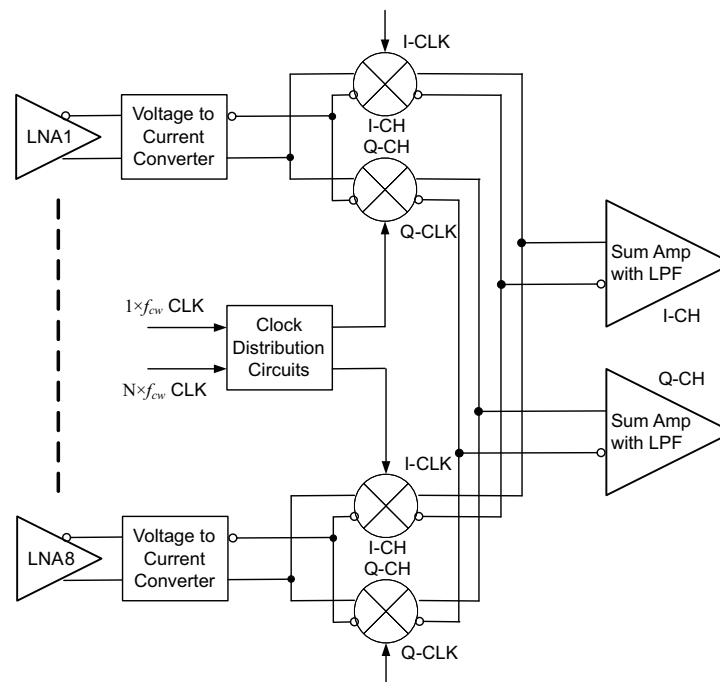

Figure 69. Simplified Block Diagram of CW Path

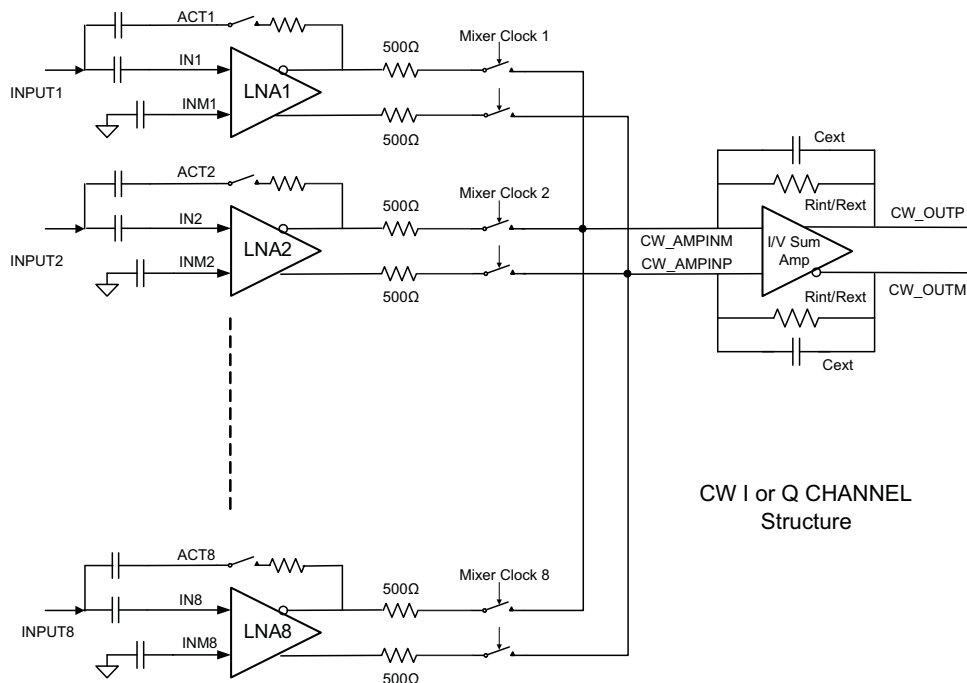

Figure 70. A Complete In-phase or Quadrature Phase Channel

The CW mixer in the AFE5808A is passive and switch based; passive mixer adds less noise than active mixers. It achieves good performance at low power. The below illustration and equations describe the principles of mixer operation, where $V_i(t)$, $V_o(t)$ and $LO(t)$ are input, output and local oscillator (LO) signals for a mixer respectively. The $LO(t)$ is square-wave based and includes odd harmonic components as the below equation expresses:

Figure 71. Block Diagram of Mixer Operation

$$V_i(t) = \sin(\omega_0 t + \omega_d t + \phi) + f(\omega_0 t)$$

$$LO(t) = \frac{4}{\pi} \left[\sin(\omega_0 t) + \frac{1}{3} \sin(3\omega_0 t) + \frac{1}{5} \sin(5\omega_0 t) \dots \right]$$

$$V_o(t) = \frac{2}{\pi} \left[\cos(\omega_d t + \phi) - \cos(2\omega_0 t - \omega_d t + \phi) \dots \right]$$

(2)

From the above equations, the 3rd and 5th order harmonics from the LO can interfere with the 3rd and 5th order harmonic signals in the $V_i(t)$; or the noise around the 3rd and 5th order harmonics in the $V_i(t)$. Therefore, the mixer's performance is degraded. In order to eliminate this side effect due to the square-wave demodulation, a proprietary harmonic suppression circuit is implemented in the AFE5808A. The 3rd and 5th harmonic components from the LO can be suppressed by over 12 dB. Thus the LNA output noise around the 3rd and 5th order harmonic bands will not be down-converted to base band. Hence, better noise figure is achieved. The

conversion loss of the mixer is about -4 dB which is derived from $20 \log_{10} \frac{2}{\pi}$

The mixed current outputs of the 8 channels are summed together internally. An internal low noise operational amplifier is used to convert the summed current to a voltage output. The internal summing amplifier is designed to accomplish low power consumption, low noise, and ease of use. CW outputs from multiple AFE5808As can be further combined on system board to implement a CW beamformer with more than 8 channels. More detail information can be found in the application information section.

Multiple clock options are supported in the AFE5808A CW path. Two CW clock inputs are required: $N \times f_{CW}$ clock and $1 \times f_{CW}$ clock, where f_{CW} is the CW transmitting frequency and N could be 16, 8, 4, or 1. Users have the flexibility to select the most convenient system clock solution for the AFE5808A. In the $16 \times f_{CW}$ and $8 \times f_{CW}$ modes, the 3rd and 5th harmonic suppression feature can be supported. Thus the $16 \times f_{CW}$ and $8 \times f_{CW}$ modes achieves better performance than the $4 \times f_{CW}$ and $1 \times f_{CW}$ modes

16 × f_{CW} Mode

The $16 \times f_{CW}$ mode achieves the best phase accuracy compared to other modes. It is the default mode for CW operation. In this mode, $16 \times f_{CW}$ and $1 \times f_{CW}$ clocks are required. $16 \times f_{CW}$ generates LO signals with 16 accurate phases. Multiple AFE5808As can be synchronized by the $1 \times f_{CW}$, i.e. LO signals in multiple AFEs can have the same starting phase. The phase noise spec is critical only for 16X clock. 1X clock is for synchronization only and doesn't require low phase noise. See the phase noise requirement in the section of application information.

The top level clock distribution diagram is shown in the below [Figure 72](#). Each mixer's clock is distributed through a 16×8 cross-point switch. The inputs of the cross-point switch are 16 different phases of the 1x clock. It is recommended to align the rising edges of the $1 \times f_{CW}$ and $16 \times f_{CW}$ clocks.

The cross-point switch distributes the clocks with appropriate phase delay to each mixer. For example, $V_i(t)$ is a received signal with a delay of $\frac{1}{16}T$, a delayed LO(t) should be applied to the mixer in order to compensate for the $\frac{1}{16}T$ delay. Thus a 22.5° delayed clock, i.e. $\frac{2\pi}{16}$, is selected for this channel. The mathematic calculation is expressed in the following equations:

$$\begin{aligned}
 V_i(t) &= \sin \left[\omega_0 \left(t + \frac{1}{16f_0} \right) + \omega_d t \right] = \sin [\omega_0 t + 22.5^\circ + \omega_d t] \\
 LO(t) &= \frac{4}{\pi} \sin \left[\omega_0 \left(t + \frac{1}{16f_0} \right) \right] = \frac{4}{\pi} \sin [\omega_0 t + 22.5^\circ] \\
 V_o(t) &= \frac{2}{\pi} \cos(\omega_d t) + f(\omega_n t)
 \end{aligned} \tag{3}$$

$V_o(t)$ represents the demodulated Doppler signal of each channel. When the doppler signals from N channels are summed, the signal to noise ratio improves.

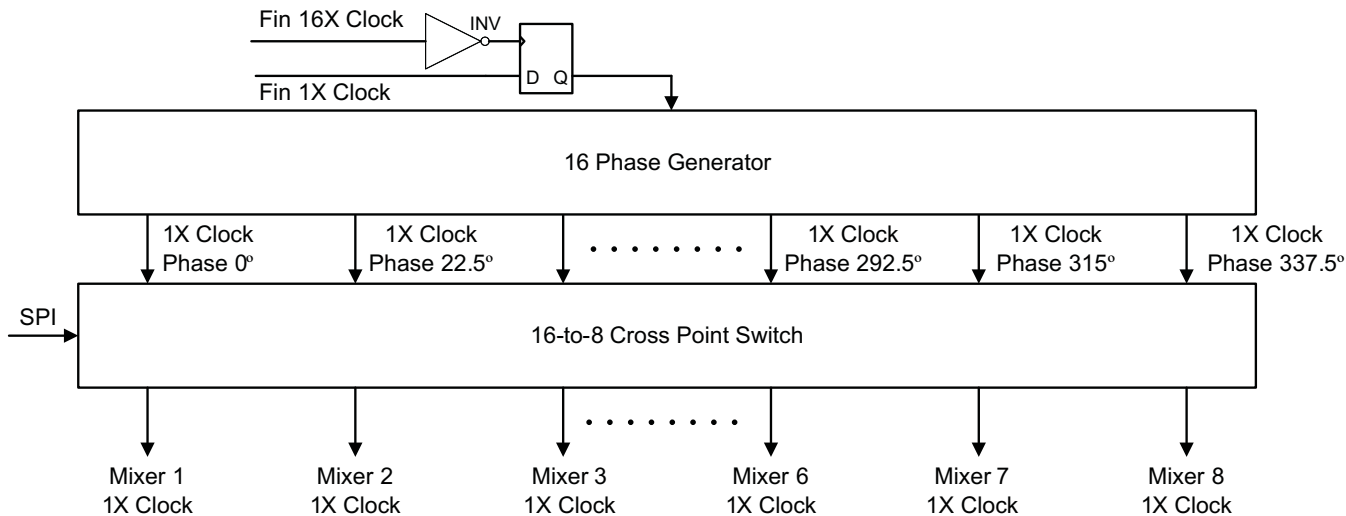

Figure 72.

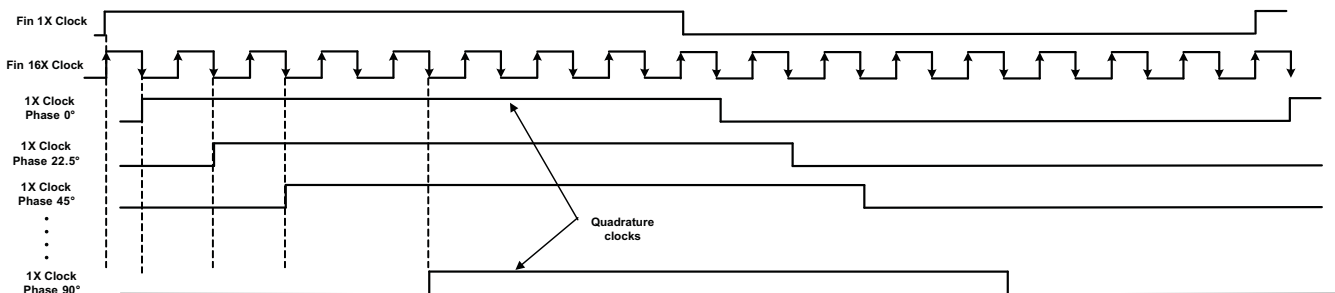

Figure 73. 1x and 16x CW Clock Timing

8 × f_{cw} and 4 × f_{cw} Modes

8 × f_{cw} and 4 × f_{cw} modes are alternative modes when higher frequency clock solution (i.e. 16 × f_{cw} clock) is not available in system. The block diagram of these two modes is shown below.

Good phase accuracy and matching are also maintained. Quadrature clock generator is used to create in-phase and quadrature clocks with exact 90° phase difference. The only difference between 8 × f_{cw} and 4 × f_{cw} modes is the accessibility of the 3rd and 5th harmonic suppression filter. In the 8 × f_{cw} mode, the suppression filter can be supported. In both modes, $\frac{1}{16}T$ phase delay resolution is achieved by weighting the in-phase and quadrature paths correspondingly. For example, if a delay of $\frac{1}{16}T$ or 22.5° is targeted, the weighting coefficients should follow the below equations, assuming I_{in} and Q_{in} are sin(ω₀t) and cos(ω₀t) respectively:

$$I_{\text{delayed}}(t) = I_{\text{in}} \cos\left(\frac{2\pi}{16}\right) + Q_{\text{in}} \sin\left(\frac{2\pi}{16}\right) = I_{\text{in}} \left(t + \frac{1}{16f_0} \right)$$

$$Q_{\text{delayed}}(t) = Q_{\text{in}} \cos\left(\frac{2\pi}{16}\right) - I_{\text{in}} \sin\left(\frac{2\pi}{16}\right) = Q_{\text{in}} \left(t + \frac{1}{16f_0} \right)$$

(4)

Therefore, after I/Q mixers, phase delay in the received signals is compensated. The mixers' outputs from all channels are aligned and added linearly to improve the signal to noise ratio. It is preferred to have the 4 × f_{cw} or 8 × f_{cw} and 1 × f_{cw} clocks aligned both at the rising edge.

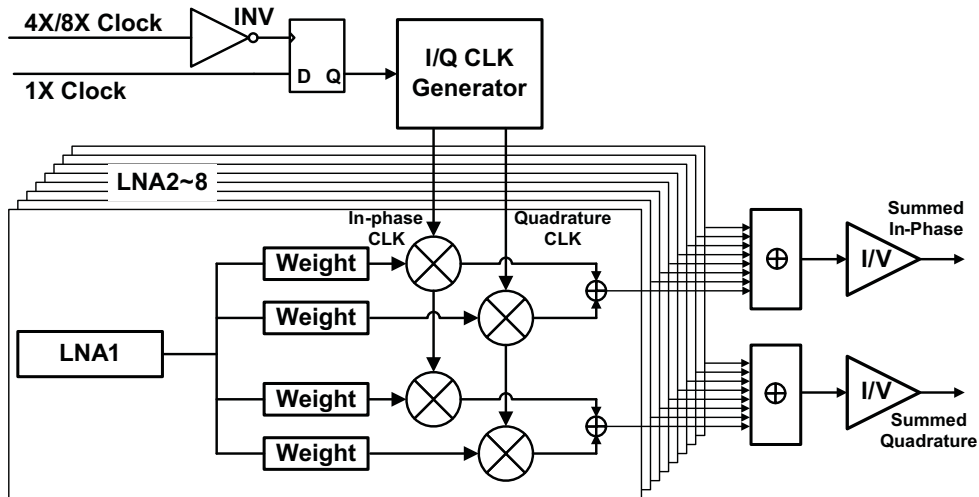

Figure 74. $8 \times f_{cw}$ and $4 \times f_{cw}$ Block Diagram

Figure 75. $8 \times f_{cw}$ and $4 \times f_{cw}$ Timing Diagram

$1 \times f_{cw}$ Mode

The $1 \times f_{cw}$ mode requires in-phase and quadrature clocks with low phase noise specifications. The $\frac{1}{16}T$ phase delay resolution is also achieved by weighting the in-phase and quadrature signals as described in the $8 \times f_{cw}$ and $4 \times f_{cw}$ modes.

APPLICATION INFORMATION

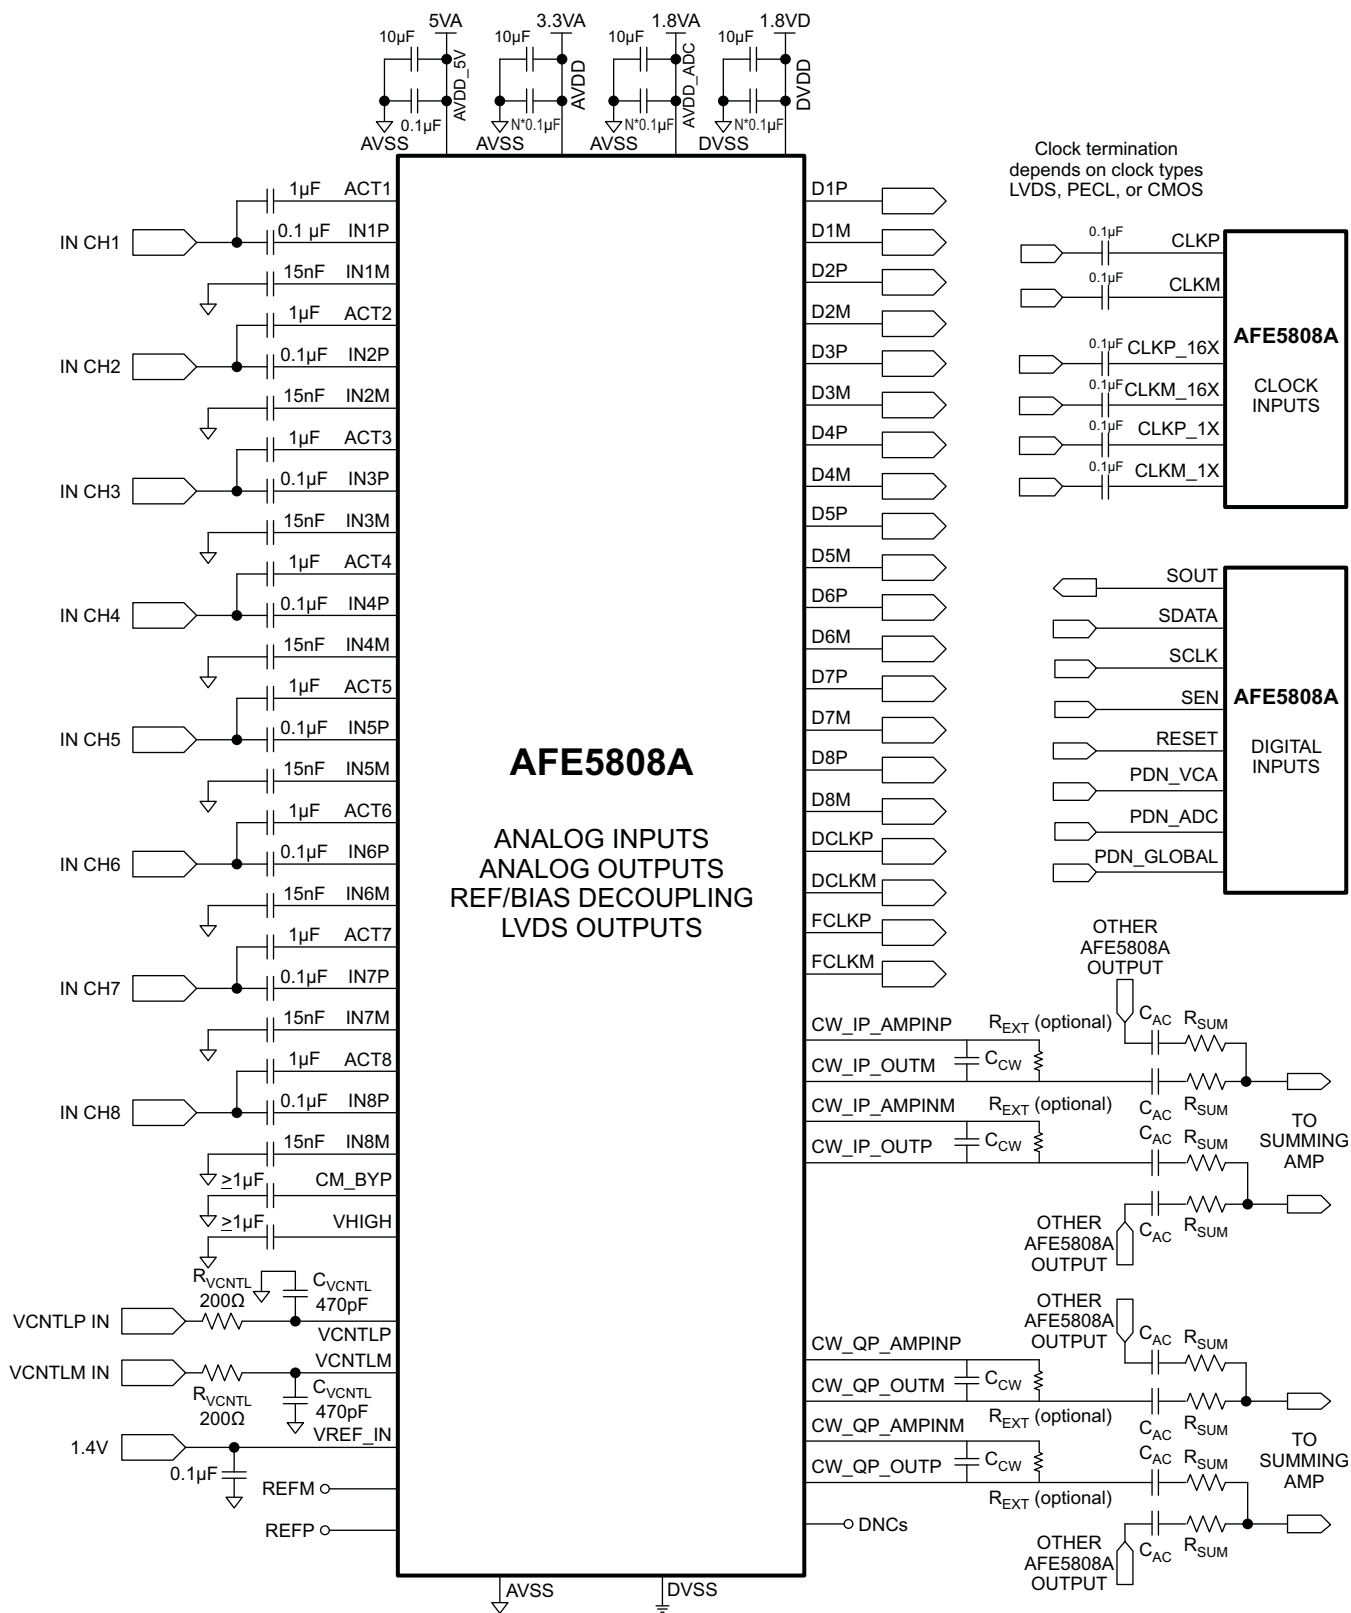

Figure 82. Application Circuit

A typical application circuit diagram is listed above. The configuration for each block is discussed below.

LNA CONFIGURATION

LNA Input Coupling and Decoupling

The LNA closed-loop architecture is internally compensated for maximum stability without the need of external compensation components. The LNA inputs are biased at 2.4 V and AC coupling is required. A typical input configuration is shown in [Figure 83](#). C_{IN} is the input AC coupling capacitor. C_{ACT} is a part of the active termination feedback path. Even if the active termination is not used, the C_{ACT} is required for the clamp functionality. Recommended values for $C_{ACT} = 1 \mu\text{F}$ and C_{IN} are $\geq 0.1 \mu\text{F}$. A pair of clamping diodes is commonly placed between the T/R switch and the LNA input. Schottky diodes with suitable forward drop voltage (e.g. the BAT754/54 series, the BAS40 series, the MMBD7000 series, or similar) can be considered depending on the transducer echo amplitude.

Figure 83. LNA Input Configurations

This architecture minimizes any loading of the signal source that may otherwise lead to a frequency-dependent voltage divider. The closed-loop design yields low offsets and offset drift. C_{BYPASS} ($\geq 0.015 \mu\text{F}$) is used to set the high-pass filter cut-off frequency and decouple the complimentary input. Its cut-off frequency is inversely proportional to the C_{BYPASS} value. The HPF cut-off frequency can be adjusted through the register 59[3:2] a [Table 11](#) lists. Low frequency signals at T/R switch output, such as signals with slow ringing, can be filtered out. In addition, the HPF can minimize system noise from DC-DC converters, pulse repetition frequency (PRF) trigger, and frame clock. Most ultrasound systems' signal processing unit includes digital high-pass filters or band-pass filters (BPFs) in FPGAs or ASICs. Further noise suppression can be achieved in these blocks. In addition, a digital HPF is available in the AFE5808A ADC. If low frequency signal detection is desired in some applications, the LNA HPF can be disabled.

Table 11. LNA HPF Settings ($C_{BYPASS} = 15 \text{ nF}$)

Reg59[3:2] (0x3B[3:2])	Frequency
00	100 KHz
01	50 KHz
10	200 KHz
11	150 KHz

CM_BYP and VHIGHS pins, which generate internal reference voltages, need to be decoupled with ≥1uF capacitors. Bigger bypassing capacitors (>2.2uF) may be beneficial if low frequency noise exists in system.

LNA Noise Contribution

The noise spec is critical for LNA and it determines the dynamic range of entire system. The LNA of the AFE5808A achieves low power and an exceptionally low-noise voltage of 0.63 nV/√Hz, and a low current noise of 2.7 pA/√Hz.

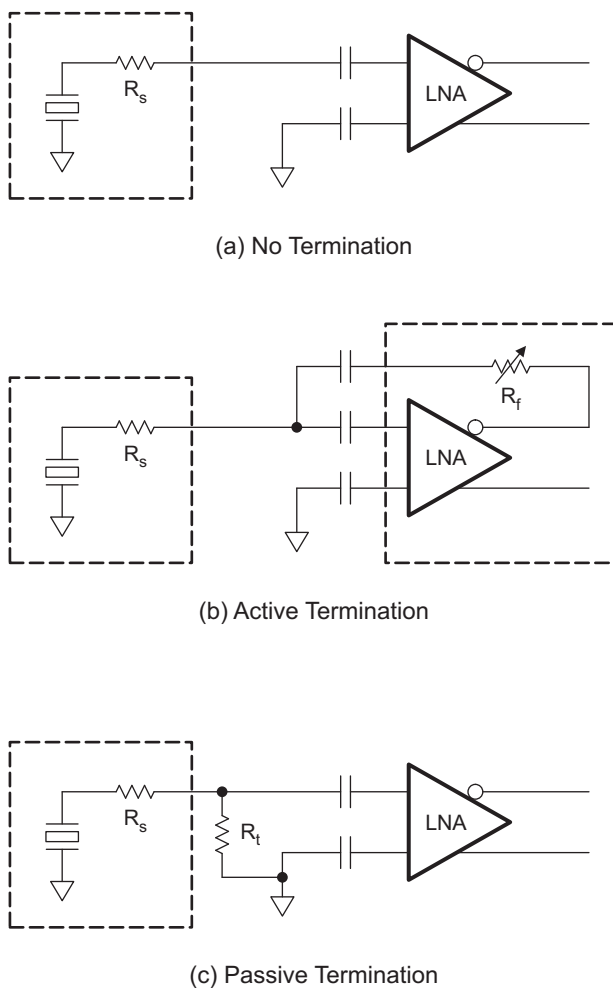

Typical ultrasonic transducer’s impedance R_s varies from tens of ohms to several hundreds of ohms. Voltage noise is the dominant noise in most cases; however, the LNA current noise flowing through the source impedance (R_s) generates additional voltage noise.

$$LNA_Noise_{total} = \sqrt{V_{LNAnoise}^2 + R_s^2 \times I_{LNAnoise}^2} \tag{5}$$

The AFE5808A achieves low noise figure (NF) over a wide range of source resistances as shown in [Figure 32](#), [Figure 33](#), and [Figure 34](#).

Active Termination

In ultrasound applications, signal reflection exists due to long cables between transducer and system. The reflection results in extra ringing added to echo signals in PW mode. Since the axial resolution depends on echo signal length, such ringing effect can degrade the axial resolution. Hence, either passive termination or active termination, is preferred if good axial resolution is desired. [Figure 84](#) shows three termination configurations:

S0499-01

Figure 84. Termination Configurations

Under the no termination configuration, the input impedance of the AFE5808A is about 6K Ω (8 K//20 pF) at 1 MHz. Passive termination requires external termination resistor R_t , which contributes to additional thermal noise.

The LNA supports active termination with programmable values, as shown in [Figure 85](#).

Figure 85. Active Termination Implementation

The AFE5808A has four pre-settings 50, 100, 200 and 400 Ω which are configurable through the registers. Other termination values can be realized by setting the termination switches shown in [Figure 85](#). Register [52] is used to enable these switches. The input impedance of the LNA under the active termination configuration approximately follows:

$$Z_{IN} = \frac{R_f}{1 + \frac{A_{V_{LNA}}}{2}} \quad (6)$$

[Table 5](#) lists the LNA R_{IN} s under different LNA gains. System designers can achieve fine tuning for different probes.

The equivalent input impedance is given by [Equation 7](#) where R_{IN} (8 K) and C_{IN} (20 pF) are the input resistance and capacitance of the LNA.

$$Z_{IN} = \frac{R_f}{1 + \frac{A_{V_{LNA}}}{2}} // C_{IN} // R_{IN} \quad (7)$$

Therefore the Z_{IN} is frequency dependent and it decreases as frequency increases shown in [Figure 10](#). Since 2 MHz–10 MHz is the most commonly used frequency range in medical ultrasound, this rolling-off effect doesn't impact system performance greatly. Active termination can be applied to both CW and TGC modes. Since each ultrasound system includes multiple transducers with different impedances, the flexibility of impedance configuration is a great plus.

[Figure 32](#), [Figure 33](#), and [Figure 34](#) shows the NF under different termination configurations. It indicates that no termination achieves the best noise figure; active termination adds less noise than passive termination. Thus termination topology should be carefully selected based on each use scenario in ultrasound.

LNA Gain Switch Response

The LNA gain is programmable through SPI. The gain switching time depends on the SPI speed as well as the LNA gain response time. During the switching, glitches might occur and they can appear as artifacts in images. LNA gain switching in a single imaging line may not be preferred, although digital signal processing might be used here for glitch suppression.

VOLTAGE-CONTROLLED-ATTENUATOR

The attenuator in the AFE5808A is controlled by a pair of differential control inputs, the $V_{CNTLM/P}$ pins. The differential control voltage spans from 0 V to 1.5 V. This control voltage varies the attenuation of the attenuator based on its linear-in-dB characteristic. Its maximum attenuation (minimum channel gain) appears at $V_{CNTLP} - V_{CNTLM} = 1.5$ V, and minimum attenuation (maximum channel gain) occurs at $V_{CNTLP} - V_{CNTLM} = 0$. The typical gain range is 40 dB and remains constant, independent of the PGA setting.

When only single-ended V_{CNTL} signal is available, this 1.5Vpp signal can be applied on the V_{CNTLP} pin with the V_{CNTLM} pin connected to ground. As shown in Figure 86, TGC gain curve is inversely proportional to the $V_{CNTLP} - V_{CNTLM}$.

(a) Single-Ended Input at V_{CNTLP}

(b) Differential Inputs at V_{CNTLP} and V_{CNTLM}

W0004-01

Figure 86. V_{CNTLP} and V_{CNTLM} Configurations

As discussed in the theory of operation, the attenuator architecture uses seven attenuator segments that are equally spaced in order to approximate the linear-in-dB gain-control slope. This approximation results in a monotonic slope; the gain ripple is typically less than ± 0.5 dB.

The control voltage input ($V_{\text{CNTLM/P}}$ pins) represents a high-impedance input. The $V_{\text{CNTLM/P}}$ pins of multiple AFE5808A devices can be connected in parallel with no significant loading effects. When the voltage level ($V_{\text{CNTLP}} - V_{\text{CNTLM}}$) is above 1.5V or below 0V, the attenuator continues to operate at its maximum attenuation level or minimum attenuation level respectively. It is recommended to limit the voltage from -0.3V to 2V.

When the AFE5808A operates in CW mode, the attenuator stage remains connected to the LNA outputs. Therefore, it is recommended to power down the VCA using the PDN_VCA register bit. In this case, $V_{\text{CNTLP}} - V_{\text{CNTLM}}$ voltage does not matter.

The AFE5808A gain-control input has a -3dB bandwidth of approximately 800KHz. This wide bandwidth, although useful in many applications (e.g. fast V_{CNTL} response), can also allow high-frequency noise to modulate the gain control input and finally affect the Doppler performance. In practice, this modulation can easily be avoided by additional external filtering (RV_{CNTL} and CV_{CNTL}) at $V_{\text{CNTLM/P}}$ pins as [Figure 81](#) shows. However, the external filter's cutoff frequency cannot be kept too low as this results in low gain response time. Without external filtering, the gain control response time is typically less than 1 μ s to settle within 10% of the final signal level of 1VPP (-6dBFS) output as indicated in [Figure 51](#) and [Figure 52](#).

Typical $V_{\text{CNTLM/P}}$ signals are generated by an 8bit to 12bit 10MSPS digital to analog converter (DAC) and a differential operation amplifier. TI's DACs, such as TLV5626 and DAC7821/11 (10MSPS/12bit), could be used to generate TGC control waveforms. Differential amplifiers with output common mode voltage control (e.g. THS4130 and OPA1632) can connect the DAC to the $V_{\text{CNTLM/P}}$ pins. The buffer amplifier can also be configured as an active filter to suppress low frequency noise. More information can be found in the literatures SLOS318F and SBAA150. The V_{CNTL} vs Gain curves can be found in [Figure 2](#). The below table also shows the absolute gain vs. V_{CNTL} , which may help program DAC correspondingly.

In PW Doppler and color Doppler modes, V_{CNTL} noise should be minimized to achieve the best close-in phase noise and SNR. Digital V_{CNTL} feature is implemented to address this need in the AFE5808A. In the digital V_{CNTL} mode, no external V_{CNTL} is needed.

Table 12. $V_{\text{CNTLP}} - V_{\text{CNTLM}}$ vs Gain Under Different LNA and PGA Gain Settings (Low Noise Mode)

$V_{\text{CNTLP}} - V_{\text{CNTLM}}$ (V)	Gain (dB) LNA = 12 dB PGA = 24 dB	Gain (dB) LNA = 18 dB PGA = 24 dB	Gain (dB) LNA = 24 dB PGA = 24 dB	Gain (dB) LNA = 12 dB PGA = 30 dB	Gain (dB) LNA = 18 dB PGA = 30 dB	Gain (dB) LNA = 24 dB PGA = 30 dB

CW OPERATION

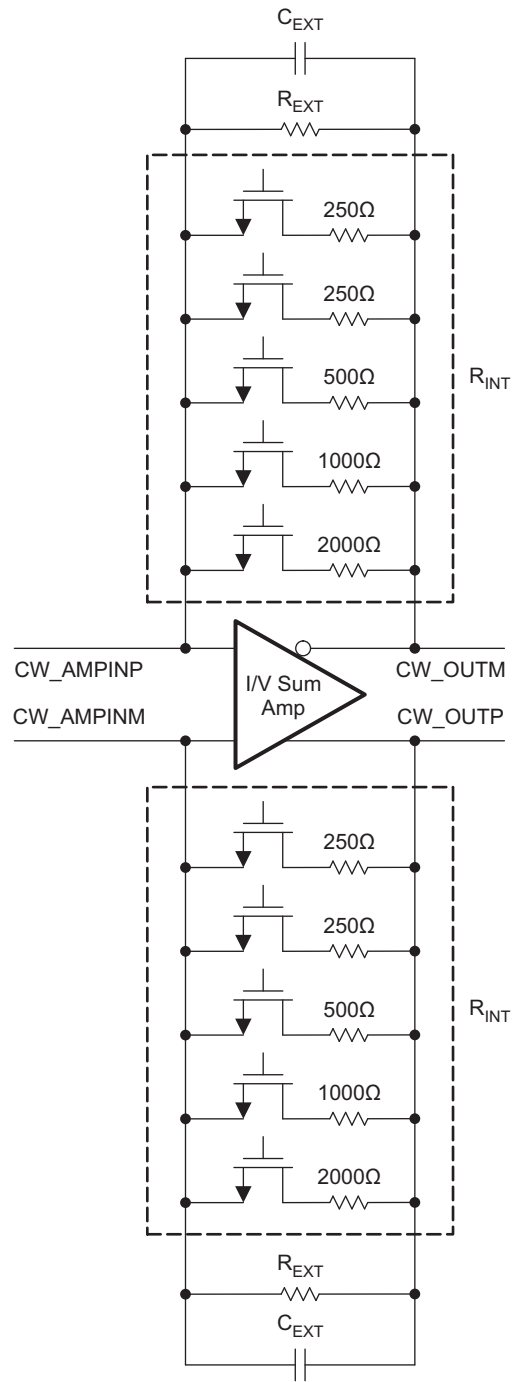

CW Summing Amplifier

In order to simplify CW system design, a summing amplifier is implemented in the AFE5808A to sum and convert 8-channel mixer current outputs to a differential voltage output. Low noise and low power are achieved in the summing amplifier while maintaining the full dynamic range required in CW operation.

This summing amplifier has 5 internal gain adjustment resistors which can provide 32 different gain settings (register 54[4:0], [Figure 85](#) and [Table 7](#)). System designers can easily adjust the CW path gain depending on signal strength and transducer sensitivity. For any other gain values, an external resistor option is supported. The gain of the summation amplifier is determined by the ratio between the 500Ω resistors after LNA and the internal or external resistor network $R_{EXT/INT}$. Thus the matching between these resistors plays a more important role than absolute resistor values. Better than 1% matching is achieved on chip. Due to process variation, the absolute resistor tolerance could be higher. If external resistors are used, the gain error between I/Q channels or among multiple AFEs may increase. It is recommended to use internal resistors to set the gain in order to achieve better gain matching (across channels and multiple AFEs). With the external capacitor C_{EXT} , this summation amplifier has 1st order LPF response to remove high frequency components from the mixers, such as $2f_0 \pm f_d$. Its cut-off frequency is determined by:

$$f_{HP} = \frac{1}{2\pi R_{INT/EXT} C_{EXT}} \quad (8)$$

Note that when different gain is configured through register 54[4:0], the LPF response varies as well.

S0501-01

Figure 87. CW Summing Amplifier Block Diagram

Multiple AFE5808As are usually utilized in parallel to expand CW beamformer channel count. These AFE5808As' CW outputs can be summed and filtered externally further to achieve desired gain and filter response. AC coupling capacitors C_{AC} are required to block DC component of the CW carrier signal. C_{AC} can vary from 1 μF to 10s μF depending on the desired low frequency Doppler signal from slow blood flow. Multiple AFE5808As' I/Q outputs can be summed together with a low noise external differential amplifiers before 16/18-bit differential audio ADCs. TI's ultralow noise differential precision amplifier OPA1632 and THS4130 are suitable devices.

S0502-01

Figure 88. CW circuit with Multiple AFE5808As

The CW I/Q channels are well matched internally to suppress image frequency components in Doppler spectrum. Low tolerance components and precise operational amplifiers should be used for achieving good matching in the external circuits as well.

CW Clock Selection

The AFE5808A can accept differential LVDS, LVPECL, and other differential clock inputs as well as single-ended CMOS clock. An internally generated VCM of 2.5V is applied to CW clock inputs, i.e. CLKP_16X/ CLKM_16X and CLKP_1X/ CLKM_1X. Since this 2.5V VCM is different from the one used in standard LVDS or LVPECL clocks, AC coupling is required between clock drivers and the AFE5808A CW clock inputs. When CMOS clock is used, CLKM_1X and CLKM_16X should be tied to ground. Common clock configurations are illustrated in Figure 89. Appropriate termination is recommended to achieve good signal integrity.

(a) LVPECL Configuration

(b) LVDS Configuration

(c) Transformer Based Configuration

(d) CMOS Configuration

S0503-01

Figure 89. Clock Configurations

The combination of the clock noise and the CW path noise can degrade the CW performance. The internal clocking circuit is designed for achieving excellent phase noise required by CW operation. The phase noise of the AFE5808A CW path is better than 155dBc/Hz at 1KHz offset. Consequently the phase noise of the mixer clock inputs needs to be better than 155dBc/Hz.

In the 16/8/4×f_{CW} operations modes, low phase noise clock is required for 16/8/4×f_{CW} clocks (i.e. CLKP_16X/CLKM_16X pins) in order to maintain good CW phase noise performance. The 1×f_{CW} clock (i.e. CLKP_1X/CLKM_1X pins) is only used to synchronize the multiple AFE5808A chips and is not used for demodulation. Thus 1×f_{CW} clock's phase noise is not a concern. However, in the 1×f_{CW} operation mode, low phase noise clocks are required for both CLKP_16X/CLKM_16X and CLKP_1X/CLKM_1X pins since both of them are used for mixer demodulation. In general, higher slew rate clock has lower phase noise; thus clocks with high amplitude and fast slew rate are preferred in CW operation. In the CMOS clock mode, 5V CMOS clock can achieve the highest slew rate.

Clock phase noise can be improved by a divider as long as the divider's phase noise is lower than the target phase noise. The phase noise of a divided clock can be improved approximately by a factor of 20logN dB where N is the dividing factor of 16, 8, or 4. If the target phase noise of mixer LO clock 1×f_{CW} is 160 dBc/Hz at 1KHz off carrier, the 16×f_{CW} clock phase noise should be better than 160 - 20log16 = 136 dBc/Hz. TI's jitter cleaners CDCM7005/CDCE72010 exceed this requirement and can be selected for the AFE5808A. In the 4X/1X modes, higher quality input clocks are expected to achieve the same performance since N is smaller. Thus the 16X mode is a preferred mode since it reduces the phase noise requirement for system clock design. In addition, the phase delay accuracy is specified by the internal clock divider and distribution circuit. Note in the 16X operation mode, the CW operation range is limited to 8 MHz due to the 16X CLK. The maximum clock frequency for the 16X CLK is 128 MHz. In the 8X, 4X, and 1X modes, higher CW signal frequencies up to 15 MHz can be supported with small degradation in performance, e.g. the phase noise is degraded by 9 dB at 15 MHz, compared to 2 MHz.

As the channel number in a system increases, clock distribution becomes more complex. It is not preferred to use one clock driver output to drive multiple AFEs since the clock buffer's load capacitance increases by a factor of N. As a result, the falling and rising time of a clock signal is degraded. A typical clock arrangement for multiple AFE5808As is illustrated in Figure 90. Each clock buffer output drives one AFE5808A in order to achieve the best signal integrity and fastest slew rate, i.e. better phase noise performance. When clock phase noise is not a concern, e.g. the 1×f_{CW} clock in the 16/8/4×f_{CW} operation modes, one clock driver output may excite more than one AFE5808As. Nevertheless, special considerations should be applied in such a clock distribution network design. In typical ultrasound systems, it is preferred that all clocks are generated from a same clock source, such as 16×f_{CW}, 1×f_{CW} clocks, audio ADC clocks, RF ADC clock, pulse repetition frequency signal, frame clock and etc. By doing this, interference due to clock asynchronization can be minimized

Figure 90. CW Clock Distribution

CW Supporting Circuits

As a general practice in CW circuit design, in-phase and quadrature channels should be strictly symmetrical by using well matched layout and high accuracy components.

In systems, additional high-pass wall filters (20Hz to 500Hz) and low-pass audio filters (10KHz to 100KHz) with multiple poles are usually needed. Since CW Doppler signal ranges from 20Hz to 20KHz, noise under this range is critical. Consequently low noise audio operational amplifiers are suitable to build these active filters for CW post-processing, e.g. OPA1632 or OPA2211. More filter design techniques can be found from www.ti.com, e.g. TI's active filter design tool <http://focus.ti.com/docs/toolsw/folders/print/filter-designer.html>

The filtered audio CW I/Q signals are sampled by audio ADCs and processed by DSP or PC. Although CW signal frequency is from 20 Hz to 20 KHz, higher sampling rate ADCs are still preferred for further decimation and SNR enhancement. Due to the large dynamic range of CW signals, high resolution ADCs (≥ 16 bit) are required, such as ADS8413 (2MSPS/16bit/92dBFS SNR) and ADS8472 (1MSPS/16bit/95dBFS SNR). ADCs for in-phase and quadrature-phase channels must be strictly matched, not only amplitude matching but also phase matching, in order to achieve the best I/Q matching. In addition, the in-phase and quadrature ADC channels must be sampled simultaneously.

ADC OPERATION

ADC Clock Configurations

To ensure that the aperture delay and jitter are the same for all channels, the AFE5808A uses a clock tree network to generate individual sampling clocks for each channel. The clock, for all the channels, are matched from the source point to the sampling circuit of each of the eight internal ADCs. The variation on this delay is described in the aperture delay parameter of the output interface timing. Its variation is given by the aperture jitter number of the same table.

Figure 91. ADC Clock Distribution Network

The AFE5808A ADC clock input can be driven by differential clocks (sine wave, LVPECL or LVDS) or singled clocks (LVCMOS) similar to CW clocks as shown in [Figure 89](#). In the single-end case, it is recommended that the use of low jitter square signals (LVCMOS levels, 1.8V amplitude). See TI document [SLYT075](#) for further details on the theory.

The jitter cleaner CDCM7005 or CDCE72010 is suitable to generate the AFE5808A's ADC clock and ensure the performance for the 14bit ADC with 77dBFS SNR. A clock distribution network is shown in [Figure 91](#).

ADC Reference Circuit

The ADC's voltage reference can be generated internally or provided externally. When the internal reference mode is selected, the REFP/M becomes output pins and should be floated. When 3[15] = 1 and 1[13] = 1, the device is configured to operate in the external reference mode in which the VREF_IN pin should be driven with a 1.4V reference voltage and REFP/M must be left open. Since the input impedance of the VREF_IN is high, no special drive capability is required for the 1.4V voltage reference

The digital beam-forming algorithm in an ultrasound system relies on gain matching across all receiver channels. A typical system would have about 12 octal AFEs on the board. In such a case, it is critical to ensure that the gain is matched, essentially requiring the reference voltages seen by all the AFEs to be the same. Matching references within the eight channels of a chip is done by using a single internal reference voltage buffer. Trimming the reference voltages on each chip during production ensures that the reference voltages are well-matched across different chips. When the external reference mode is used, a solid reference plane on a printed circuit board can ensure minimal voltage variation across devices. More information on voltage reference design can be found in the document [SLYT339](#). The dominant gain variation in the AFE5808A comes from the VCA gain variation. The gain variation contributed by the ADC reference circuit is much smaller than the VCA gain variation. Hence, in most systems, using the ADC internal reference mode is sufficient to maintain good gain matching among multiple AFE5808As. In addition, the internal reference circuit without any external components achieves satisfactory thermal noise and phase noise performance.

POWER MANAGEMENT

Power/Performance Optimization

The AFE5808A has options to adjust power consumption and meet different noise performances. This feature would be useful for portable systems operated by batteries when low power is more desired. Refer to characteristics information listed in the table of electrical characteristics as well as the typical characteristic plots.

Power Management Priority

Power management plays a critical role to extend battery life and ensure long operation time. The AFE5808A has fast and flexible power down/up control which can maximize battery life. The AFE5808A can be powered down/up through external pins or internal registers. The following table indicates the affected circuit blocks and priorities when the power management is invoked. The higher priority controls can overwrite the lower priority ones. In the device, all the power down controls are logically ORed to generate final power down for different blocks. Thus, the higher priority controls can cover the lower priority ones. The AFE5808A register settings are maintained when the AFE5808A is in either partial power down mode or complete power down mode.

Table 13. Power Management Priority

	Name	Blocks	Priority
Pin	PDN_GLOBAL	All	High
Pin	PDN_VCA	LNA + VCAT+ PGA	Medium
Register	VCA_PARTIAL_PDN	LNA + VCAT+ PGA	Low
Register	VCA_COMPLETE_PDN	LNA + VCAT+ PGA	Medium
Pin	PDN_ADC	ADC	Medium
Register	ADC_PARTIAL_PDN	ADC	Low
Register	ADC_COMPLETE_PDN	ADC	Medium
Register	PDN_VCAT_PGA	VCAT + PGA	Lowest
Register	PDN_LNA	LNA	Lowest

Partial Power-Up/Down Mode

The partial power up/down mode is also called as fast power up/down mode. In this mode, most amplifiers in the signal path are powered down, while the internal reference circuits remain active as well as the LVDS clock circuit, i.e. the LVDS circuit still generates its frame and bit clocks.

The partial power down function allows the AFE5808A to be wake up from a low-power state quickly. This configuration ensures that the external capacitors are discharged slowly; thus a minimum wake-up time is needed as long as the charges on those capacitors are restored. The VCA wake-up response is typically about 2 μ s or 1% of the power down duration whichever is larger. The longest wake-up time depends on the capacitors connected at INP and INM, as the wake-up time is the time required to recharge the caps to the desired operating voltages. For 0.1 μ F at INP and 15nF at INM can give a wake-up time of 2.5ms. For larger capacitors this time will be longer. The ADC wake-up time is about 1 μ s. Thus the AFE5808A wake-up time is more dependent on the VCA wake-up time. This also assumes that the ADC clock has been running for at least 50 μ s before normal operating mode resumes. The power-down time is instantaneous, less than 1.0 μ s.

This fast wake-up response is desired for portable ultrasound applications in which the power saving is critical. The pulse repetition frequency of a ultrasound system could vary from 50KHz to 500Hz, while the imaging depth (i.e., the active period for a receive path) varies from 10 μ s to hundreds of us. The power saving can be pretty significant when a system's PRF is low. In some cases, only the VCA would be powered down while the ADC keeps running normally to ensure minimal impact to FPGAs.

In the partial power-down mode, the AFE5808A typically dissipates only 26mW/ch, representing an 80% power reduction compared to the normal operating mode. This mode can be set using either pins (PDN_VCA and PDN_ADC) or register bits (VCA_PARTIAL_PDN and ADC_PARTIAL_PDN).

Complete Power-Down Mode

To achieve the lowest power dissipation of 0.7 mW/CH, the AFE5808A can be placed into a complete power-down mode. This mode is controlled through the registers ADC_COMPLETE_PDN, VCA_COMPLETE_PDN or PDN_GLOBAL pin. In the complete power-down mode, all circuits including reference circuits within the AFE5808A are powered down; and the capacitors connected to the AFE5808A are discharged. The wake-up time depends on the time needed to recharge these capacitors. The wake-up time depends on the time that the AFE5808A spends in shutdown mode. 0.1 μ F at INP and 15nF at INM can give a wake-up time close to 2.5ms.

Power Saving in CW Mode

Usually only half the number of channels in a system are active in the CW mode. Thus the individual channel control through ADC_PDN_CH <7:0> and VCA_PDN_CH <7:0> can power down unused channels and save power consumption greatly. Under the default register setting in the CW mode, the voltage controlled attenuator, PGA, and ADC are still active. During the debug phase, both the PW and CW paths can be running simultaneously. In real operation, these blocks need to be powered down manually.

TEST MODES

The AFE5808A includes multiple test modes to accelerate system development. The ADC test modes have been discussed in the register description section.

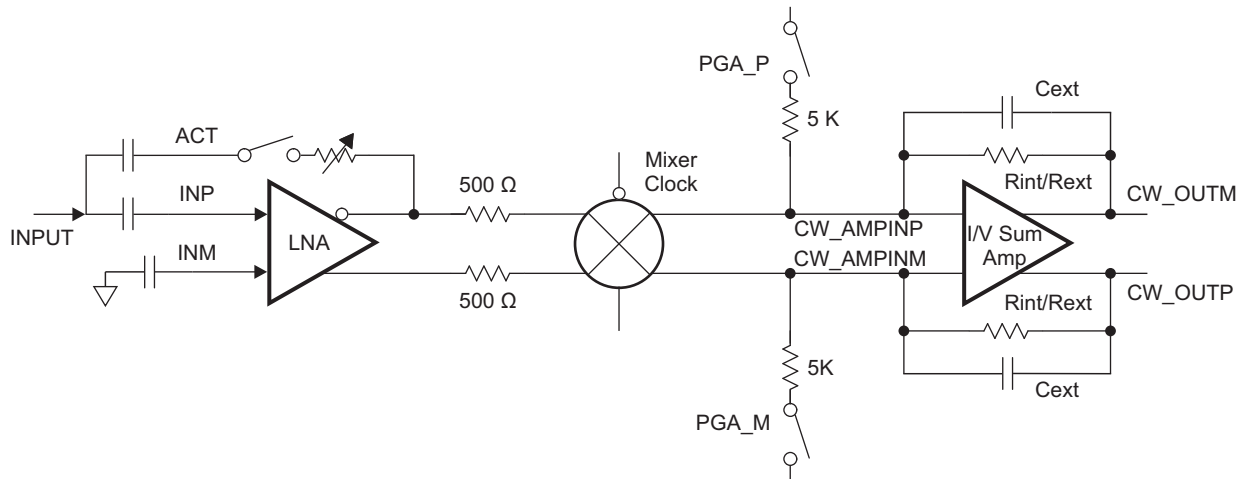

The VCA has a test mode in which the CH7 and CH8 PGA outputs can be brought to the CW pins. By monitoring these PGA outputs, the functionality of VCA operation can be verified. The PGA outputs are connected to the virtual ground pins of the summing amplifier (CW_IP_AMPINM/P, CW_QP_AMPINM/P) through 5k Ω resistors. The PGA outputs can be monitored at the summing amplifier outputs when the LPF capacitors C_{EXT} are removed. Note that the signals at the summing amplifier outputs are attenuated due to the 5K Ω resistors. The attenuation coefficient is R_{INT/EXT}/5k Ω .

If users would like to check the PGA outputs without removing CEXT, an alternative way is to measure the PGA outputs directly at the CW_IP_AMPINM/P and CW_QP_AMPINM/P when the CW summing amplifier is powered down.

Two register bits are related to this test mode:

- PGA Test Mode Enable
 - Reg59[9]=1

- CW Summing Amplifier Power Down
 - Reg59[8]=0

S0504-01

Figure 92. AFE5808A PGA Test Mode

POWER SUPPLY, GROUNDING AND BYPASSING

In a mixed-signal system design, power supply and grounding design plays a significant role. The AFE5808A distinguishes between two different grounds: AVSS(Analog Ground) and DVSS(digital ground). In most cases, it should be adequate to lay out the printed circuit board (PCB) to use a single ground plane for the AFE5808A. Care should be taken that this ground plane is properly partitioned between various sections within the system to minimize interactions between analog and digital circuitry. Alternatively, the digital (DVDD) supply set consisting of the DVDD and DVSS pins can be placed on separate power and ground planes. For this configuration, the AVSS and DVSS grounds should be tied together at the power connector in a star layout. In addition, optical isolator or digital isolators, such as ISO7240, can separate the analog portion from the digital portion completely. Consequently they prevent digital noise to contaminate the analog portion. Table 13 lists the related circuit blocks for each power supply.

Table 14. Supply vs Circuit Blocks

POWER SUPPLY	GROUND	CIRCUIT BLOCKS
AVDD (3.3VA)	AVSS	LNA, attenuator, PGA with current clamp and BPF, reference circuits, CW summing amplifier, CW mixer, VCA SPI
AVDD_5V (5VA)	AVSS	LNA, CW clock circuits, reference circuits
AVDD_ADC (1.8VA)	AVSS	ADC analog and reference circuits
DVDD (1.8VD)	DVSS	LVDS and ADC SPI

All bypassing and power supplies for the AFE5808A should be referenced to their corresponding ground planes. All supply pins should be bypassed with 0.1µF ceramic chip capacitors (size 0603 or smaller). In order to minimize the lead and trace inductance, the capacitors should be located as close to the supply pins as possible. Where double-sided component mounting is allowed, these capacitors are best placed directly under the package. In addition, larger bipolar decoupling capacitors 2.2µF to 10µF, effective at lower frequencies) may also be used on the main supply pins. These components can be placed on the PCB in proximity (< 0.5 in or 12.7 mm) to the AFE5808A itself.

The AFE5808A has a number of reference supplies needed to be bypassed, such as CM_BYP, VHIGH, and VREF_IN. These pins should be bypassed with at least 1µF; higher value capacitors can be used for better low-frequency noise suppression. For best results, choose low-inductance ceramic chip capacitors (size 0402, > 1µF) and place them as close as possible to the device pins.

High-speed mixed signal devices are sensitive to various types of noise coupling. One primary source of noise is the switching noise from the serializer and the output buffer/drivers. For the AFE5808A, care has been taken to ensure that the interaction between the analog and digital supplies within the device is kept to a minimal amount. The extent of noise coupled and transmitted from the digital and analog sections depends on the effective inductances of each of the supply and ground connections. Smaller effective inductance of the supply and ground pins leads to improved noise suppression. For this reason, multiple pins are used to connect each supply and ground sets. It is important to maintain low inductance properties throughout the design of the PCB layout by use of proper planes and layer thickness.

BOARD LAYOUT

Proper grounding and bypassing, short lead length, and the use of ground and power-supply planes are particularly important for high-frequency designs. Achieving optimum performance with a high-performance device such as the AFE5808A requires careful attention to the PCB layout to minimize the effects of board parasitics and optimize component placement. A multilayer PCB usually ensures best results and allows convenient component placement. In order to maintain proper LVDS timing, all LVDS traces should follow a controlled impedance design. In addition, all LVDS trace lengths should be equal and symmetrical; it is recommended to keep trace length variations less than 150mil (0.150 in or 3.81mm).

In addition, appropriate delay matching should be considered for the CW clock path, especially in systems with high channel count. For example, if clock delay is half of the 16x clock period, a phase error of 22.5° could exist. Thus the timing delay difference among channels contributes to the beamformer accuracy.

Additional details on BGA PCB layout techniques can be found in the Texas Instruments Application Report MicroStar BGA Packaging Reference Guide ([SSYZ015B](#)), which can be downloaded from [www.ti.com](#).

REVISION HISTORY

Changes from Original (October 2011) to Revision A	Page
• Moved footnote "Low Noise Mode/Medium Power Mode/Low Power Mode" to the test condition for Input Referred Current Noise	6
• Changed CW signal carrier freq From 8 MHz Max To 8 Hz typical	8
• Changed CW Clock freq, 4X CLK From 32 MHz Max To 32 Hz typical	8
• Added footnote for CW Operation Range	8
• Added text to the ADC Register Map section	27
• Added text to the CW Clock Selection section	57
• Added text to the Power Management Priority section	59

AFE5808AZCF	ACTIVE	NFBGA	ZCF	135	160	Green (RoHS & no Sb/Br)	SNAGCU	Level-3-260C-168 HR	

⁽¹⁾ The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

⁽³⁾ MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

ZCF (R-PBGA-N135)

PLASTIC BALL GRID ARRAY

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994 .
 - B. This drawing is subject to change without notice.
 - C. This is a lead-free solder ball design.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
